Homework 4 – due November 30, 2018 by 5:00pm

1. An abrupt Si p^+n diode has $N_D = 10^{16} \text{ cm}^{-3}$ on the n side and $N_A = 10^{17} \text{ cm}^{-3}$ on the p side. For Si at room temperature, $E_G = 1.1 \text{ eV}$, $N_C = 2.8 \times 10^{19} \text{ cm}^{-3}$, and $N_V = 1.8 \times 10^{19} \text{ cm}^{-3}$. Assume the minority carrier lifetime is $8 \mu\text{s}$ (for both electrons and holes), the electron mobility is $1400 \text{ cm}^2/\text{V}\cdot\text{s}$, and the hole mobility is $500 \text{ cm}^2/\text{V}\cdot\text{s}$.
 - (a) Find the depletion region widths under zero bias on the p -side (w_{p0}) and on the n -side (w_{n0}), and the total depletion width $w_{tot,0}$.
 - (b) If a forward bias of 0.2 V is applied, find the resulting depletion widths (w_p , w_n , and w_{tot}), the electron current density J_n through the depletion region, the hole current density J_p through the depletion region, and the total current density J_{tot} through the diode.

2. For the diode in Problem 1:
 - (a) If the doping on the n -side is increased by a factor of 2, by what percentage do $w_{tot,0}$ and w_{tot} change? How about if instead the doping on the p -side was increased by a factor of 2?
 - (b) What is the percent change in the current calculated in Problem 1(b) if the doping on the n -side is increased by a factor of 2? What about if the doping on the p -side is increased by a factor of 2?
 - (c) For diodes in which one side is much more heavily doped than the other, what does this tell you about the effects of varying the doping on the heavily doped side versus varying the doping on the lightly doped side?

3. Problem 5.13 in Streetman.

4. Assume that a p^+n diode is built with a quasi-neutral n region having a width l which is smaller than the hole diffusion length ($l < L_p$). This is a so-called *narrow base diode*. Since for this case holes are injected into a short n region under forward bias, we cannot use the boundary condition $\delta p(x' = \infty) = 0$, as in Eq. 4-35 in Streetman. Instead, our boundary condition becomes $\delta p(x' = l) = 0$. (where x' is the x -coordinate having its origin at the depletion edge x_n).
 - (a) Solve the continuity equation for this case to obtain:
$$\delta p(x') = \frac{\Delta p_n [e^{(l-x')/L_p} - e^{-(l-x')/L_p}]}{e^{l/L_p} - e^{-l/L_p}}$$
 - (b) If $l \ll L_p$, show that this equation becomes $\delta p(x') = \Delta p_n (1 - x'/l)$. [i.e., hole profile is linear]

5. Reading Assignment: *Streetman*: Ch. 5 (sections 5.2 and 5.3)
