 - \Rightarrow Problem 2.19
 - \Rightarrow Problem 2.20
- ⇒ Reminder HW #2 due Thursday Oct. 18

Non-Linear Schrodinger Equation

- Both linear (dispersive) and nonlinear effects must be taken into account for pulse propagation in the fiber
- ⇒ The propagation of a signal in a single mode fiber is set (to a very high level of accuracy) by the following equation, called the nonlinear Schrodinger equation:

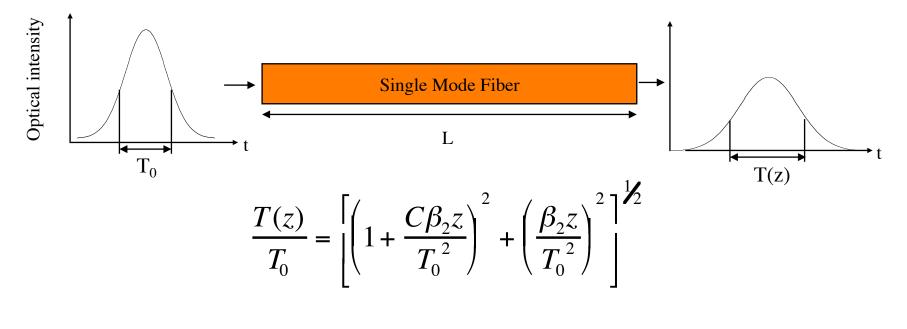

- \Rightarrow A(z,t) is the complex-envelope of the optical field
- \Rightarrow The resulting optical power is $P(z,t) = |A(z,t)|^2$

ECE 228A Fall 2008 Daniel J. Blumenthal

Pulse Broadening

Assuming a Gaussian shaped input pulse and first order dispersion dominates ($\beta_2 \neq 0$)

Define Dispersion Length

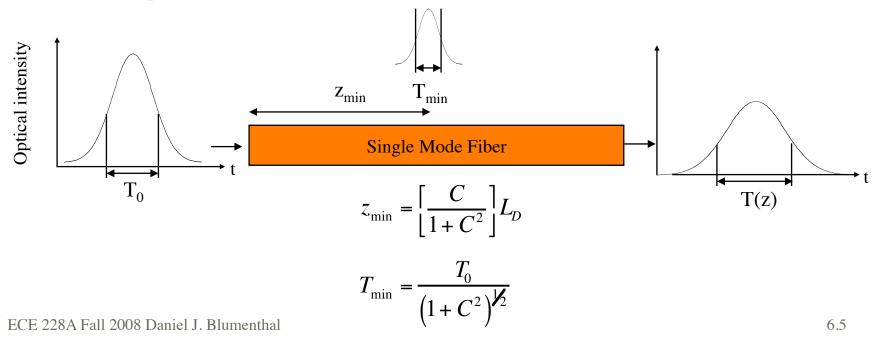

An unchirped pulse (C=0) will broaden by a factor of $\sqrt{2}$ at z = L_D

Pulse Compression

If $\beta_2 C < 0$, the pulse will initially decrease!

This will happen if the

- (a) the initial pulse is positively chirped and propagates in the anomolous dispersion regime of the fiber OR
- (b) if the pulse is initially negatively chirped and propagates in the normal dispersion regime of the fiber

Chromatic Dispersion

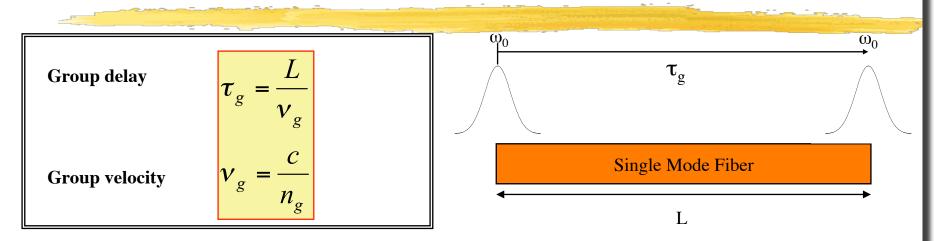

- ⇒ The two terms β_2 and β_3 of the previous equation are the derivative of the "mode propagation constant" $\beta(\omega)$
- \Rightarrow The meaning of $\beta(\omega)$ is clear when considering a single pulse propagation

$$\beta(\omega) = \frac{\omega n(\omega)}{c} = \beta_0 + \beta_1 \Delta \omega + \frac{1}{2} \beta_2 \Delta \omega^2 + \frac{1}{6} \beta_3 \Delta \omega^3$$
$$v_p = \frac{\omega_0}{\beta_0} = \frac{c}{n(\omega_0)}$$
$$v_g = \frac{1}{\beta_1} = \left(\frac{d\beta}{d\omega}\Big|_{\omega=\omega_0}\right)^{-1}$$

 \Rightarrow It turns out that, considering the dispersion term only

- \Rightarrow The **phase velocity** (v_p) is the velocity of the center frequency ω_0 ,
- ⇒ The group velocity (v_g) is the velocity of the center of the pulse. It is the value that determine the practical "velocity" of the transmission of the information (energy) in the fiber

Group Delay

- ⇒ The group delay effective index n_g is approx. of the same order of the index of refraction of the fiber, i.e., $n_g = 1.5$
- \Rightarrow As an example, the (group) delay of 100 Km of fiber is given by:

$$\tau_g = \frac{L}{v_g} = \frac{Ln_g}{c} = \frac{10^5 \cdot 1.5}{3 \cdot 10^8} \cong 500 \ \mu s$$
$$v_g = \frac{c}{n_g} \cong 2 \cdot 10^8 \ m/s$$

6.7

Group Velocity Dispersion (GVD)

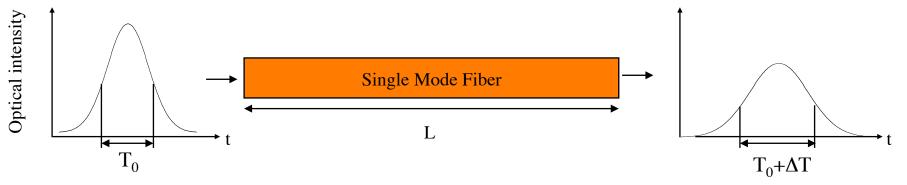

- \Rightarrow Group velocity (GVD) is frequency-dependent
- \Rightarrow Any communication signal (pulse) has a given bandwidth
 - ⇒ Different frequencies in pulse => Different group delays => Leads to pulse distortion
- A more quantitative analysis can be carried out by considering that the fiber acts as a filter with the following transfer function:

$$A(z,\omega) = A(0,\omega) \cdot e^{-j\left(\frac{\beta_2}{2}\omega^2 + \frac{\beta_3}{2}\omega^3\right)z}$$

- This equation is obtained after some mathematical manipulation that extracts" the absolute group delay
- \Rightarrow The coefficient β_2 and β_3 are evaluated on the pulse central frequency/wavelength ω_0

Group Velocity Dispersion (GVD)

⇒ The previous equation can be exactly solved in some particular cases, among which the most important one is the propagation of a Gaussian pulse

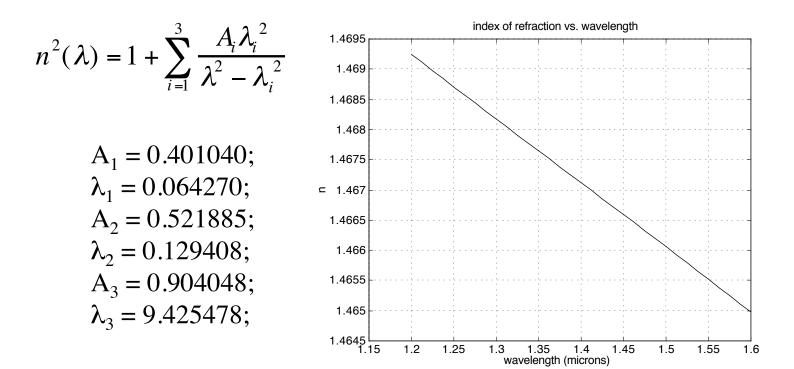

⇒ The Gaussian pulse is broadened after propagation of distance L by the amount:

$$\Delta T = L |\beta_2| \Delta \omega$$

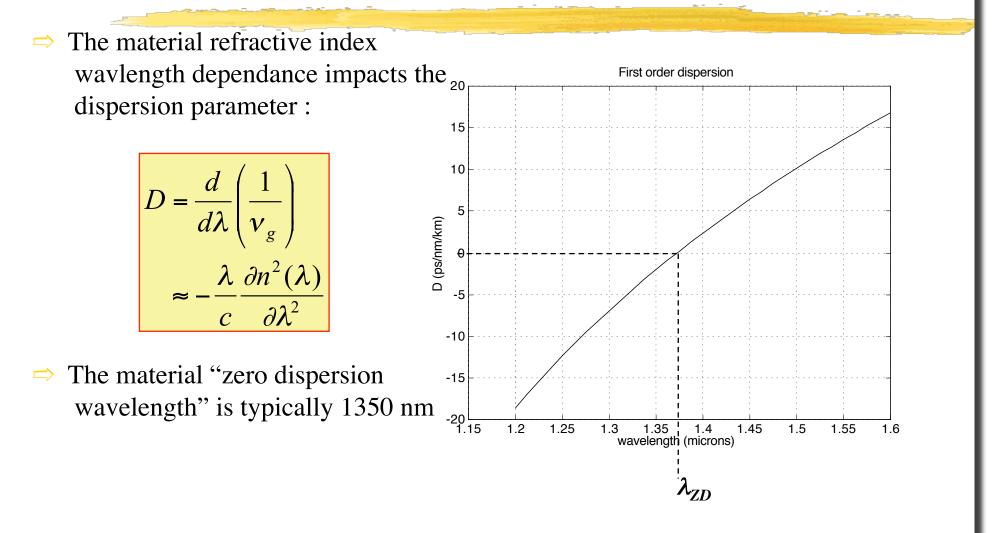

- \Rightarrow where $\Delta \omega$ is the spectrum occupied by the pulse
- $\Rightarrow \alpha v \delta \beta_2$ is the dispersion (material and waveguide) of the fiber

Refractive Index of Silica Fibers

⇒ The index of refraction of bulk silica can be approximated using the Sellmeir equation with experimentally measured parameters.

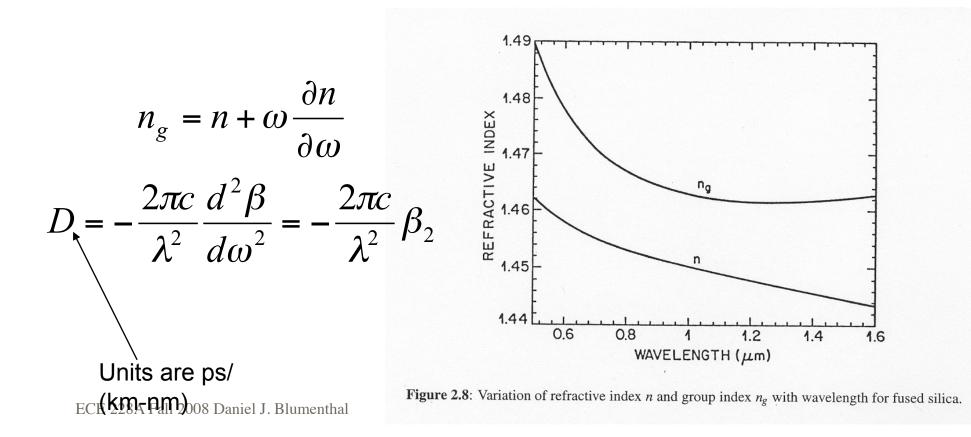

Material Dispersion Parameter

Group-Velocity Dispersion ⇒ The index of the mode is dependent on the wavelength (i.e. the fiber is dispersive).

- Two components: material dispersion and waveguide dispersion. \Rightarrow
- These contribute to phase index. \Rightarrow
- The group index is given by \Rightarrow

Dispersion parameters: β_2 and D

- ⇒ β₂ is called the "group velocity dispersion" GVD parameter
 ⇒ It is expressed in units of ps²/km
- ⇒ From a mathematical point of view, it is easier to handle equations dealing with β_2 and optical frequency
- ⇒ It is also convenient to specify dispersion in terms of optical wavelength
- \Rightarrow The "D" parameter is

$$D = \frac{d}{d\lambda} \left(\frac{1}{v_g} \right) \approx -\frac{\lambda}{c} \frac{\partial n^2(\lambda)}{\partial \lambda^2}$$

⇒ D is called the "Dispersion parameter", and it is expressed in units of ps /nm-km

The Dispersion Parameter D

 \Rightarrow The relation between the two parameters is given by:

$$D = -2\pi C/\lambda^2 \beta_2 [ps/nm-km]$$

⇒ Physical meaning: given two wavelengths separated by $\Delta\lambda$, their different group velocities give rise to a (group) delay between the two components given by

$$\Delta_{delay} = D L \Delta \lambda$$

 \Rightarrow The gaussian pulse spread, in terms of *D*, is given by:

$$\Delta T = L |D| \Delta \lambda$$

where $\Delta \lambda$ is the spectral width of the gaussian pulse

Frequency Dependance of Dispersion

- ⇒ The frequency dependence of $\beta(\omega)$ is determined by the following physical effects:
 - ⇒ Material dispersion
 - \Rightarrow The index of refraction of the *bulk* material depends on frequency
 - ⇒ Waveguide dispersion
 - \Rightarrow Even for an ideal material with constant index of refraction, the solution of the Maxwell equation for a single mode propagating into a fiber gives a frequency-dependent $\beta(\omega)$
 - ⇒ This waveguide effects depends on the profile of the index of refraction of the fiber
- \Rightarrow The actual $\beta(\omega)$ is thus a combination of the two effects

General Dispersion Formula

If we take into account more realistic source and fiber effects *

we include β₃
 source with a generic spectral width σ_ω

$$\frac{\sigma(z)}{\sigma_0} = \left[\left(1 + \frac{C\beta_2 z}{2\sigma_0^2} \right)^2 + \left(1 + V^2 \right) \left(\frac{\beta_2 z}{2\sigma_0^2} \right)^2 + \left(1 + C^2 + V^2 \right)^2 \frac{1}{2} \left(\frac{\beta_3 z}{4\sigma_0^3} \right)^2 \right]^{\frac{1}{2}}$$

Where $V = 2\sigma_0 \sigma_\omega$

⇒ This formula can be used to derive dispersion limits in several different transmission scenarios
