## Intro to Queueing Theory

$\Rightarrow$ A simple queue model is shown below. It handles data packets that arrive at an average rate of $\lambda$ packets/time.
$\Rightarrow$ The packets queue up for service in the buffer and are served (according to some service discipline) to the output at an average rate of $\mu$ packets/time.
$\Rightarrow$ Define link utilization or traffic intensity ( $\rho$ ) as

$$
\rho \equiv \frac{\lambda}{\mu}
$$

## Performance

$\Rightarrow$ We are interested the dependence on $\mu$ and the buffer size on the time delay, blocking performance and packet throughput.
$\Rightarrow$ These performance parameters depend on the probability of state
of the queue.
$\Rightarrow$ In order to determine the probability of state of the queue we need
to know
$\Rightarrow$ The packet arrival process (or statistics)
$\Rightarrow$ The packet length distribution
$\Rightarrow$ The queue service discipline (for example, FCFS, FIFO, LCFS)

## M/M/1 Queue

$\Rightarrow A n M / M / 1$ queue is a single server queue, that assumes Poisson packet arrival, exponential service-time statistics and FIFO service $\Rightarrow A / B / C$ denotes $A=$ Arrival distribution, $B=$ Service distribution and $\mathrm{C}=$ Number of servers used.
$\Rightarrow$ M stands for Markov process which translates to Poisson arrival statistics and exponential inter-packet arrival (or transmission).
$\Rightarrow$ Probabilities of state are denoted $\boldsymbol{p}_{n}$, which is the probability that there are $\boldsymbol{n}$ customers (packets) at the queue. This number includes that packet that is currently being served.
$\Rightarrow$ We assume in steady state that the $\boldsymbol{p}_{\boldsymbol{n}}$ do not change with time.

## Buffer Occupancy State

$\Rightarrow$ The probability $\boldsymbol{p}_{\boldsymbol{n}}(\boldsymbol{t}+\Delta \boldsymbol{t})$ that there are $\boldsymbol{n}$ customers in the queue at time $t+$ $\Delta t$, derives from the probability $p_{\mathrm{n}}(\mathrm{t})$.
$\Rightarrow$ If queue was in state $\boldsymbol{n}$ at time $\boldsymbol{t}+\boldsymbol{\Delta t}$, it only could have been in states $\boldsymbol{n}-\mathbf{1}$, $\boldsymbol{n}$ or $\boldsymbol{n}+\boldsymbol{1}$ at time $\boldsymbol{t}$.
$\Rightarrow$ The probability of being in state $\boldsymbol{n}$ at time $\boldsymbol{t}+\boldsymbol{\Delta t}$ is given by the sum of the mutually exclusive probabilities that the queue was in state $\boldsymbol{n - 1}, \boldsymbol{n}$ or $\boldsymbol{n}+\boldsymbol{1}$ at time $\boldsymbol{t}$ each weighted by the independent probability of arriving at state $\boldsymbol{n}$ in $\boldsymbol{\Delta}$ $t$ units of time.

## M/M/1 Queue Occupancy State

$$
\begin{aligned}
& p_{n}(t+\Delta t)=p_{n}(t)[(1-\lambda \Delta t)(1-\mu \Delta t)+\mu \Delta t \lambda \Delta t+O(\Delta t)] \\
& \left.+p_{n-1}(t)[\lambda \Delta t](1-\mu \Delta t)+O(\Delta t)\right] \\
& \left.+p_{n+1}(t)[\mu \Delta t](1-\lambda \Delta t)+O(\Delta t)\right] \\
& \text { Dropping terms } O(\Delta t) \\
& p_{n}(t+\Delta t)=[1-(\lambda+\mu) \Delta t] p_{n}(t)+\lambda \Delta t p_{n-1}(t)+\mu \Delta t p_{n+1}(t)
\end{aligned}
$$

Expanding $p_{n}(t+\Delta t)$ in a Taylor Series, we can write as a difference function

$$
\begin{aligned}
& p_{n}(t+\Delta t)=p_{n}(t)+\frac{d p_{n}(t)}{d t} \Delta t \\
& \frac{d p_{n}(t)}{d t}=-(\lambda+\mu) p_{n}(t)+\lambda p_{n-1}(t)+\mu p_{n+1}(t)
\end{aligned}
$$

For steady state

$$
\begin{aligned}
& \frac{d p_{n}(t)}{d t}=0 \\
& (\lambda+\mu) p_{n}=\lambda p_{n-1}+\mu p_{n+1}, n \geq 1
\end{aligned}
$$

## Steady State

$\Rightarrow$ The solution to the steady state equation yields a Geometric Distribution for the steady $\mathrm{M} / \mathrm{M} / 1$ infinite queue state probability distribution.

$$
\lambda p_{n}=\mu p_{n+1}
$$

or for n processes

$p_{n}=\rho^{n} p_{0}$
$\rho \equiv \frac{\lambda}{\mu}$
or for an infinite queue

$$
\begin{aligned}
& p_{0}=(1-\rho) \\
& p_{n}=(1-\rho) \rho^{n} \text { for } \rho \equiv \frac{\lambda}{\mu}<1
\end{aligned}
$$
