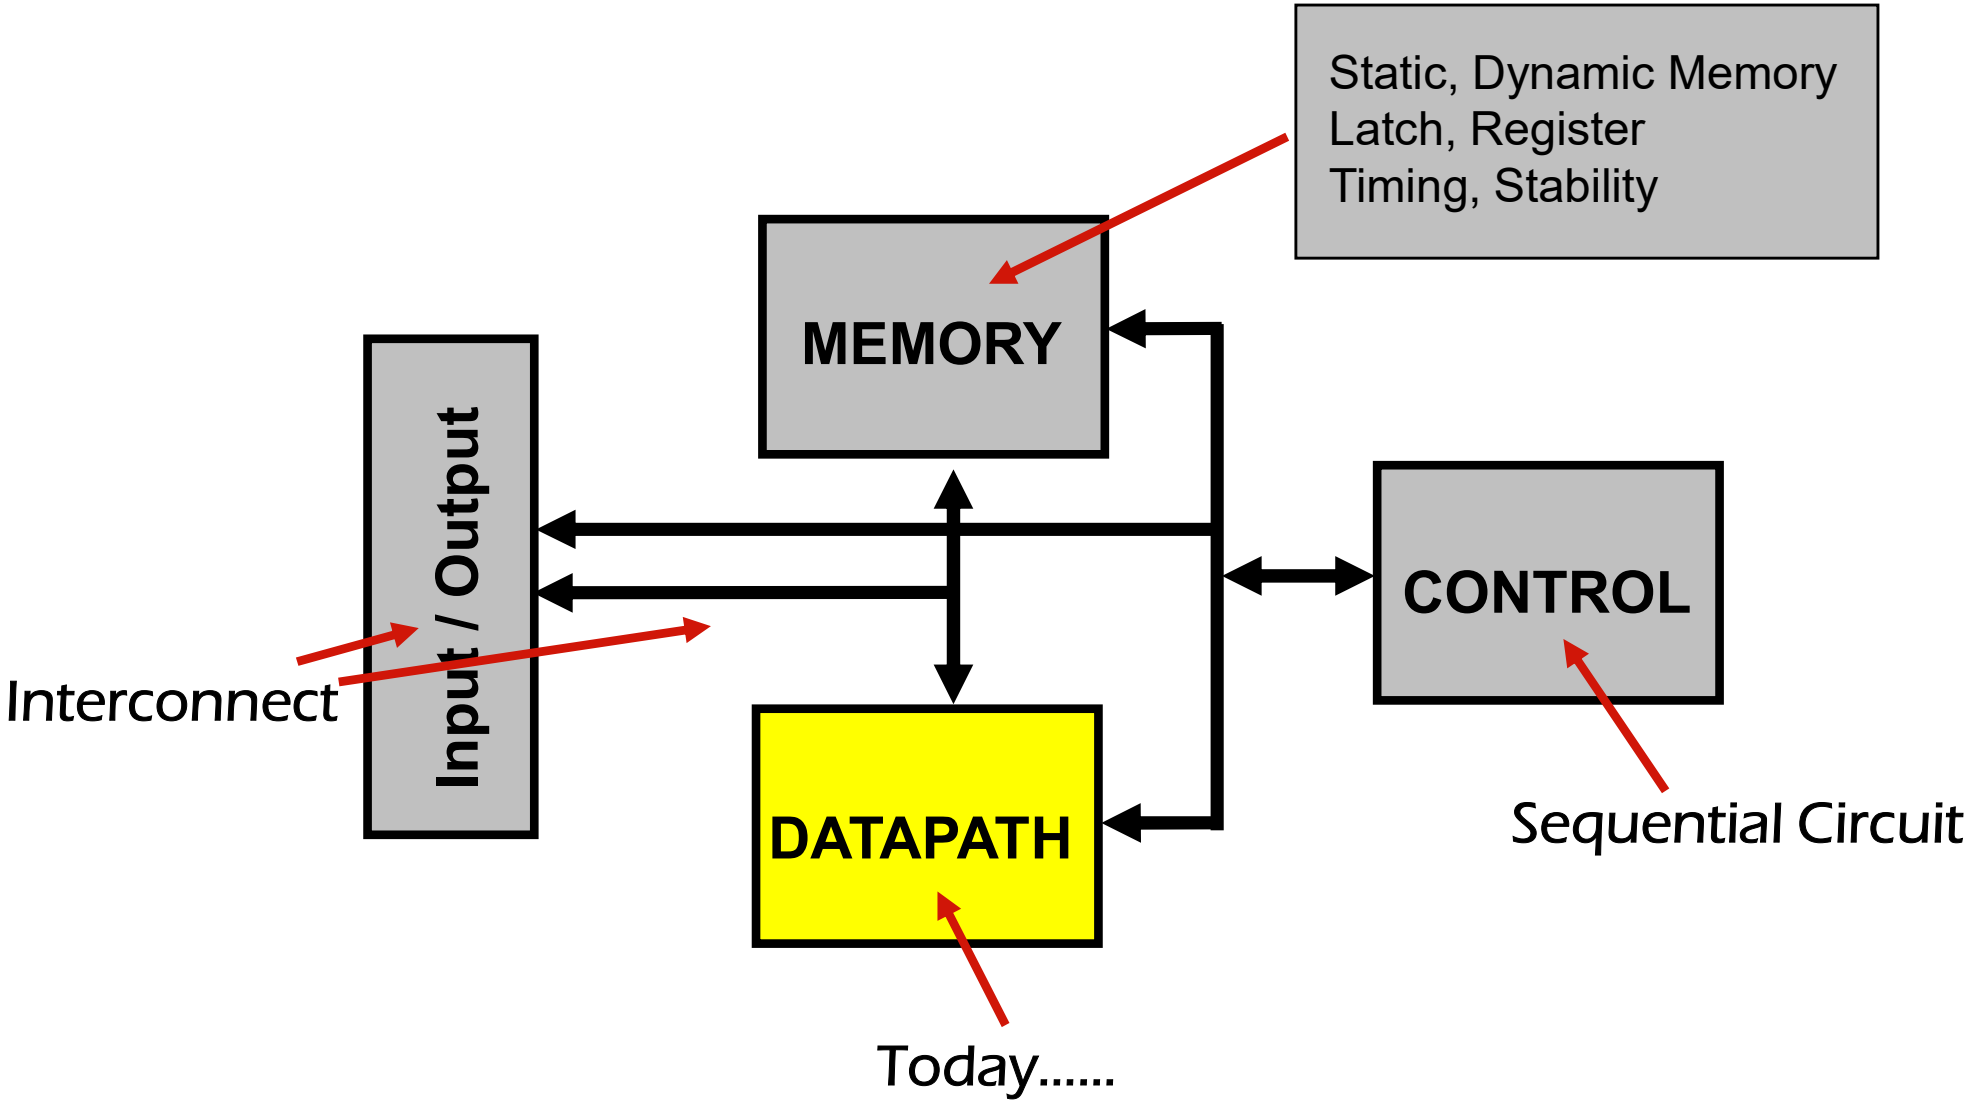
A Generic Digital Processor



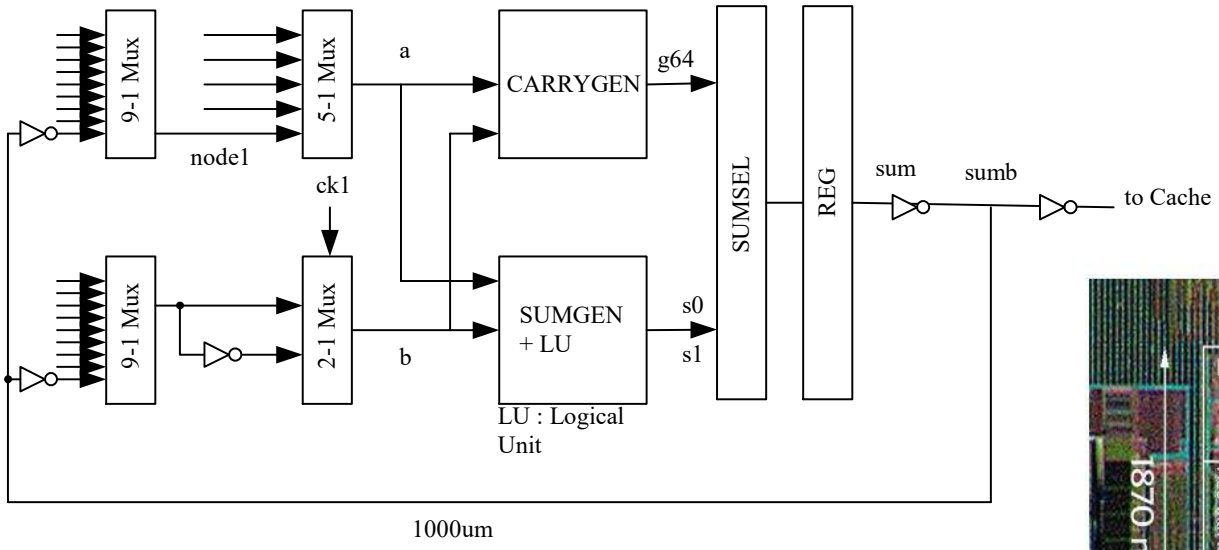
DATAPATH

- The core of a digital Processor

  where all computations are performed

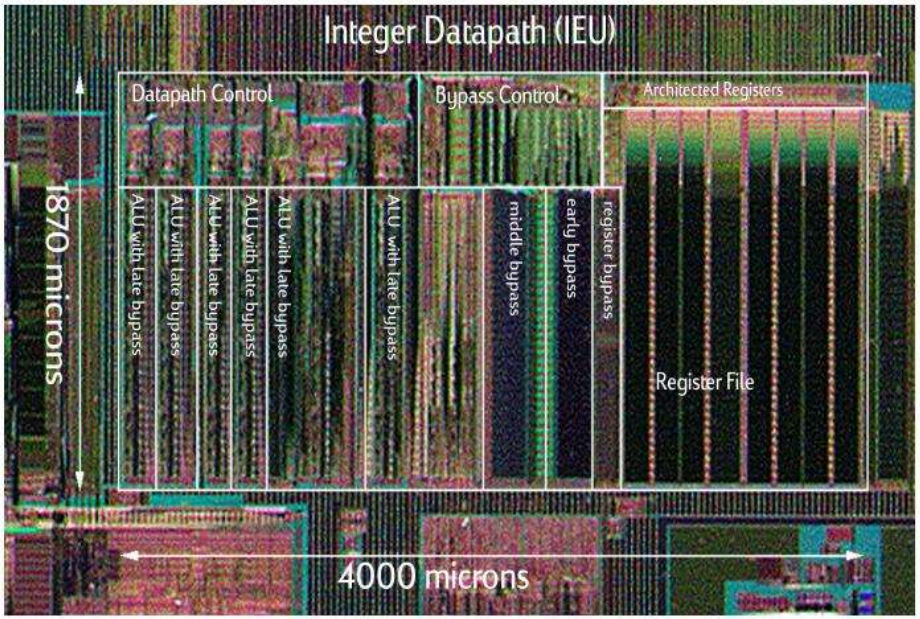
- Datapath consists
  - **Logic Blocks**
    - Combinational Logic Functions (AND, OR, XOR….)
  - **Arithmetic Blocks**
    - **Addition**
    - **Multiplication**
    - **Comparison**
    - **Shift**

An Intel Microprocessor



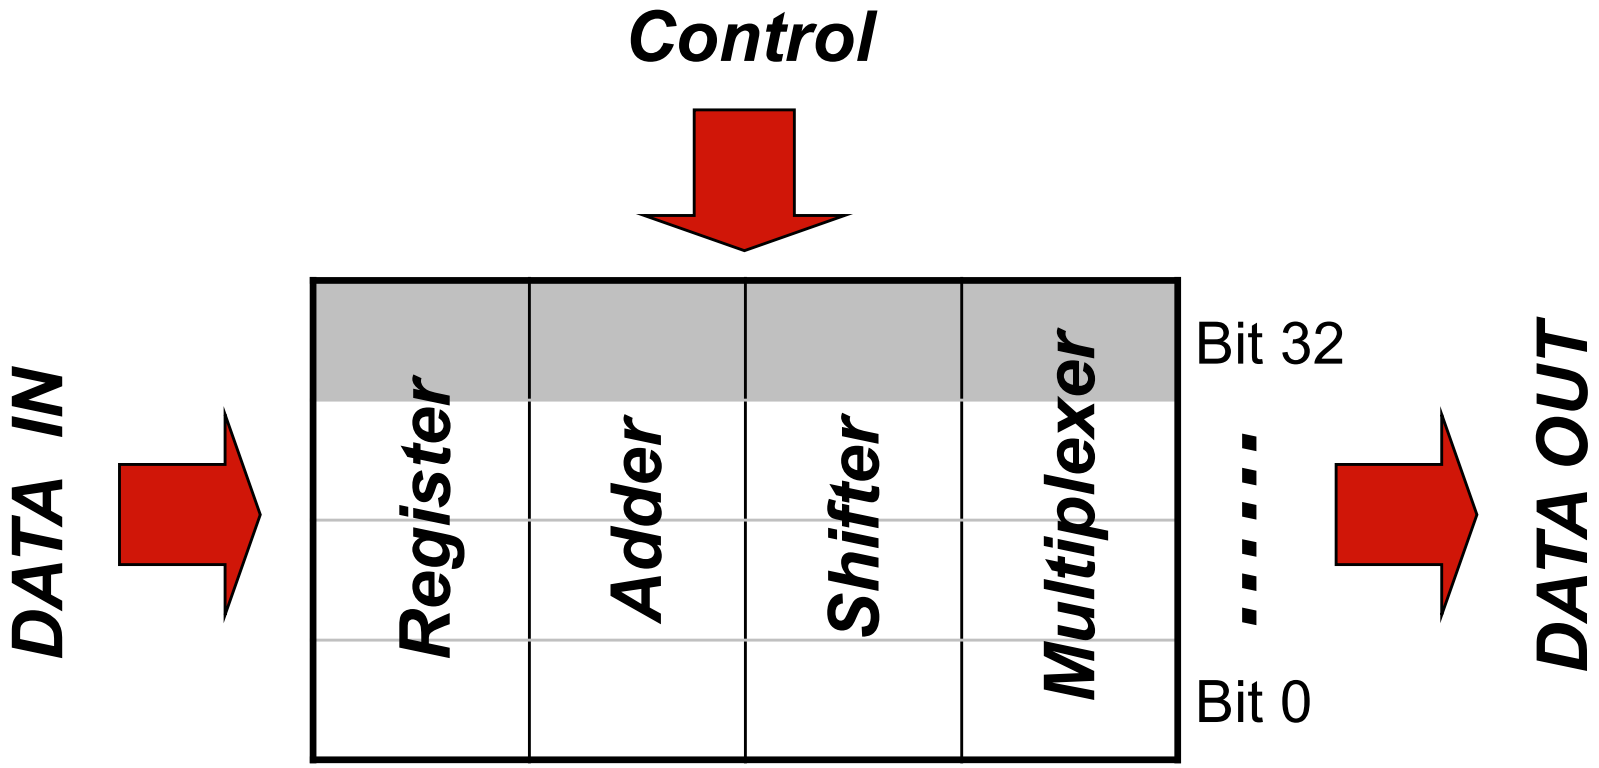
Itanium has 6 integer execution units like this

Intel Itanium®
Integer Datapath



Fetzer, Orton, ISSCC'02

Bit-Sliced Design



Design a single bit datapath and repeat for all bits

Adders

Design an Adder

- Fundamental Arithmetic Building Block
- Performance
  - Logic Level Optimization
    - Optimize Boolean Functions
    - Carry Lookahead
  - Circuit Level Optimization
    - Transistor Sizing
- Power Consumption

Fundamental Logic of Adders

- Truth table of a full adder
  - Sum: $S = A \oplus B \oplus Cin$
  - Carry out:

  $Cout = (A \bullet B) + (Cin \bullet (A \oplus B))$

A	B	C	C_{out}	S
0	0	0	0	0
0	0	1	0	1
0	1	0	0	1
0	1	1	1	0
1	0	0	0	1
1	0	1	1	0
1	1	0	1	0
1	1	1	1	1

- PGK (independent of Cin)
  - Generate: $G = A \bullet B$
  - Propagate: $P = A \oplus B$
  - Kill: $K = \sim A \bullet \sim B$

  $S = P \oplus Cin$, $Cout = G + Cin \bullet P$

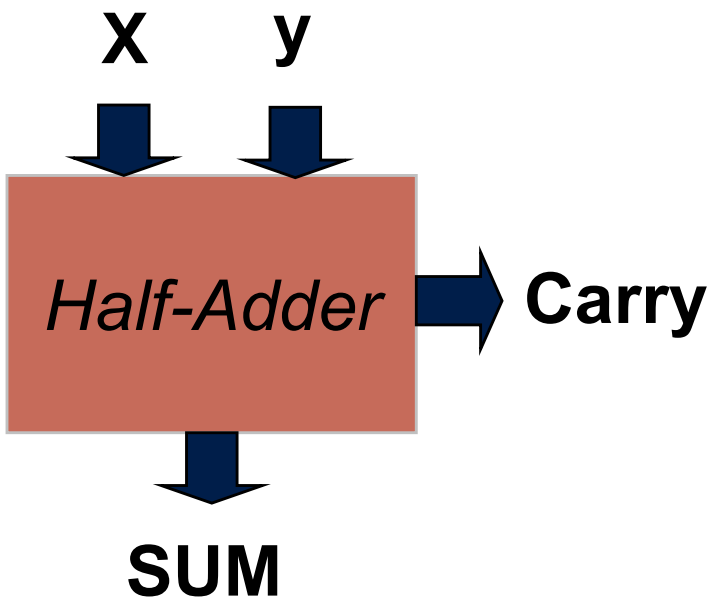
Adder Overview

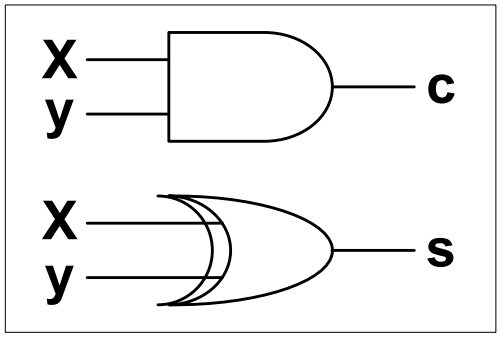
- Different adders covered in the slides:

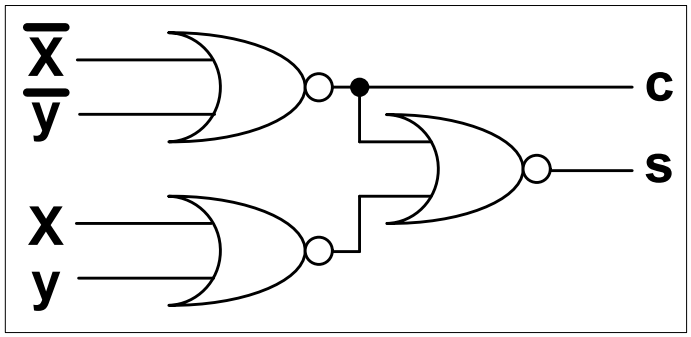
- ***Single-bit adder***
  - *Static*
    - *Static CMOS*
    - *Mirror design*
    - *Transmission gate*
  - *Dynamic*
    - *Manchester chain*
- ***Multi-bit adder***
  - *Ripple-carry adder*
  - *Carry bypass adder*
    - *Linear carry select*
    - *Square-root carry select*
  - *Carry look-ahead*

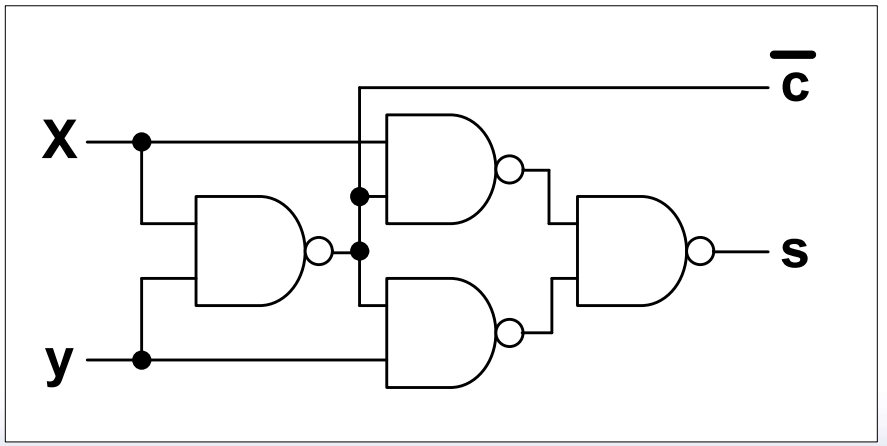
Half-Adder Implementations

Half-Adder

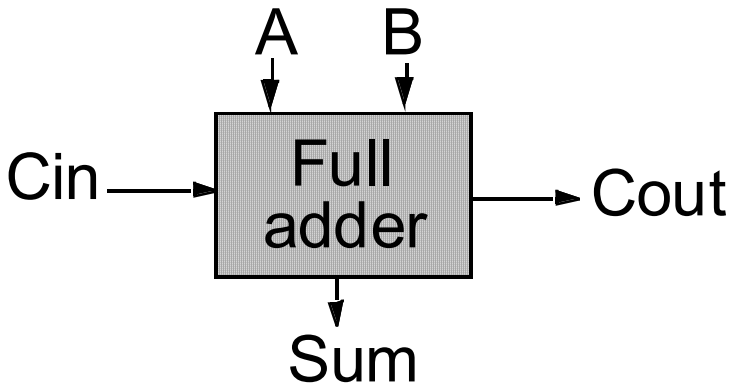


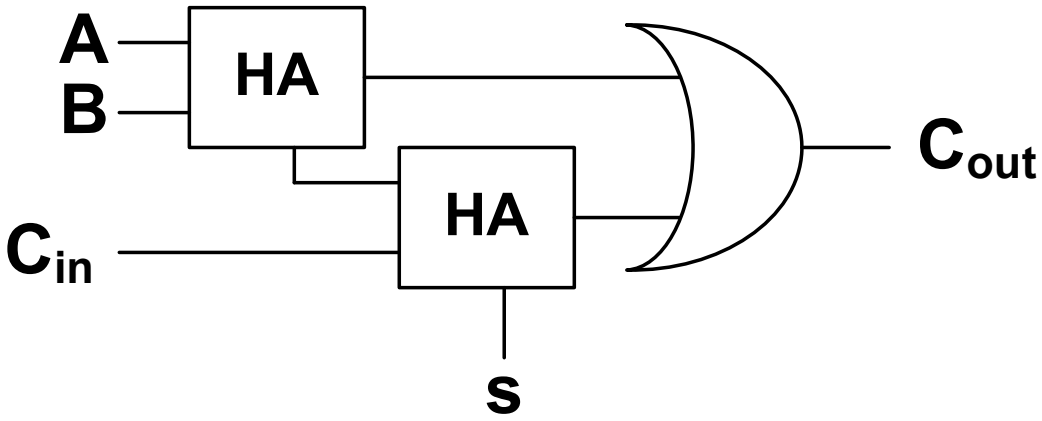






Full-Adder

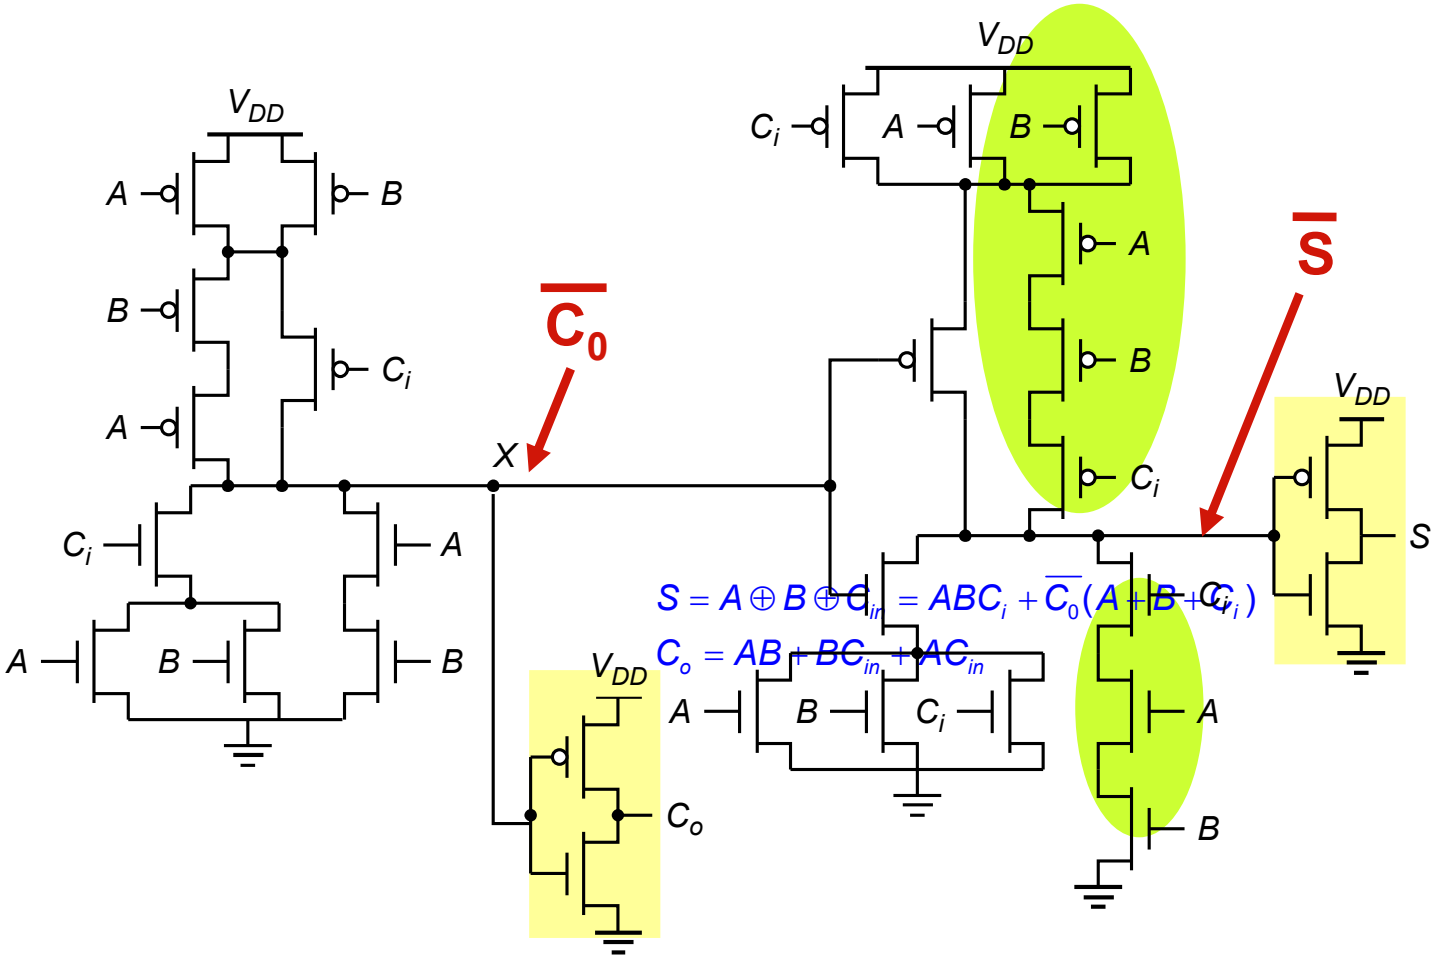




$$S = A \oplus B \oplus C_{in} = A\overline{B}\overline{C}_{in} + \overline{A}B\overline{C}_{in} + \overline{A}\overline{B}C_{in} + ABC_{in}$$

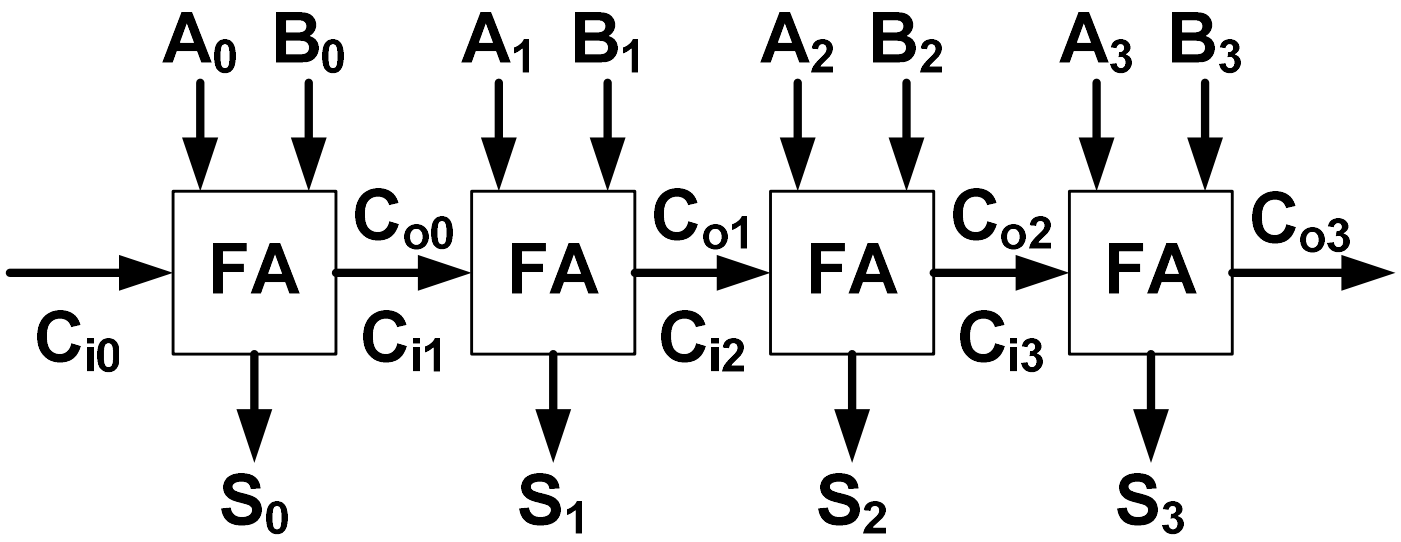
$$C_{out} = AB + BC_{in} + AC_{in}$$

Complimentary Static CMOS Full Adder



28 Transistors

The Ripple-Carry Adder

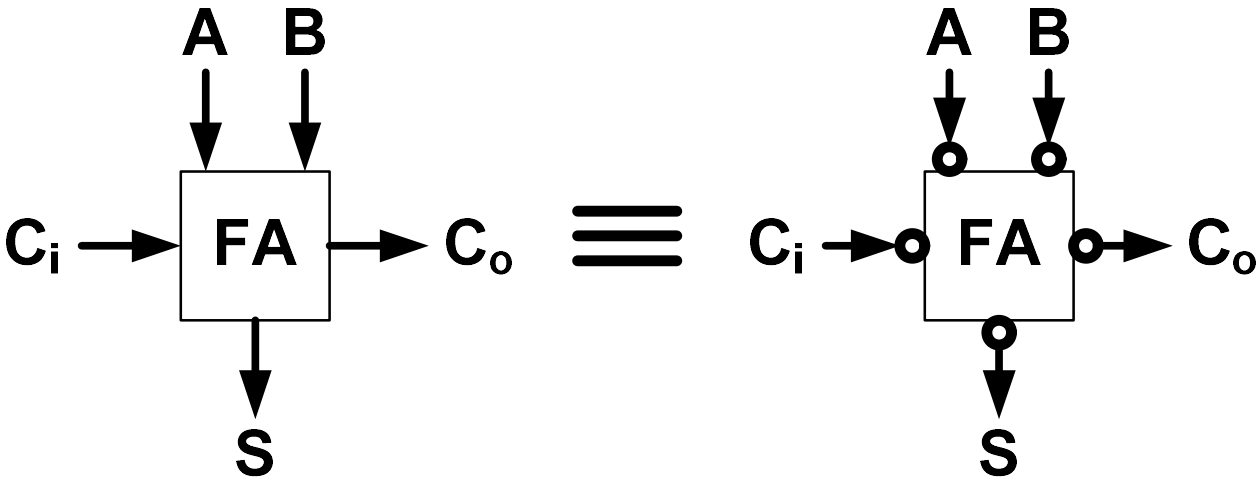


Worst case delay: linear with the number of bits $t_d = O(N)$

$$t_{adder} \sim (N\text{-}1)t_{carry} + t_{sum}$$

- Propagation Delay is proportional to N
- t_{carry} dominates the propagation delay

Inverting Property

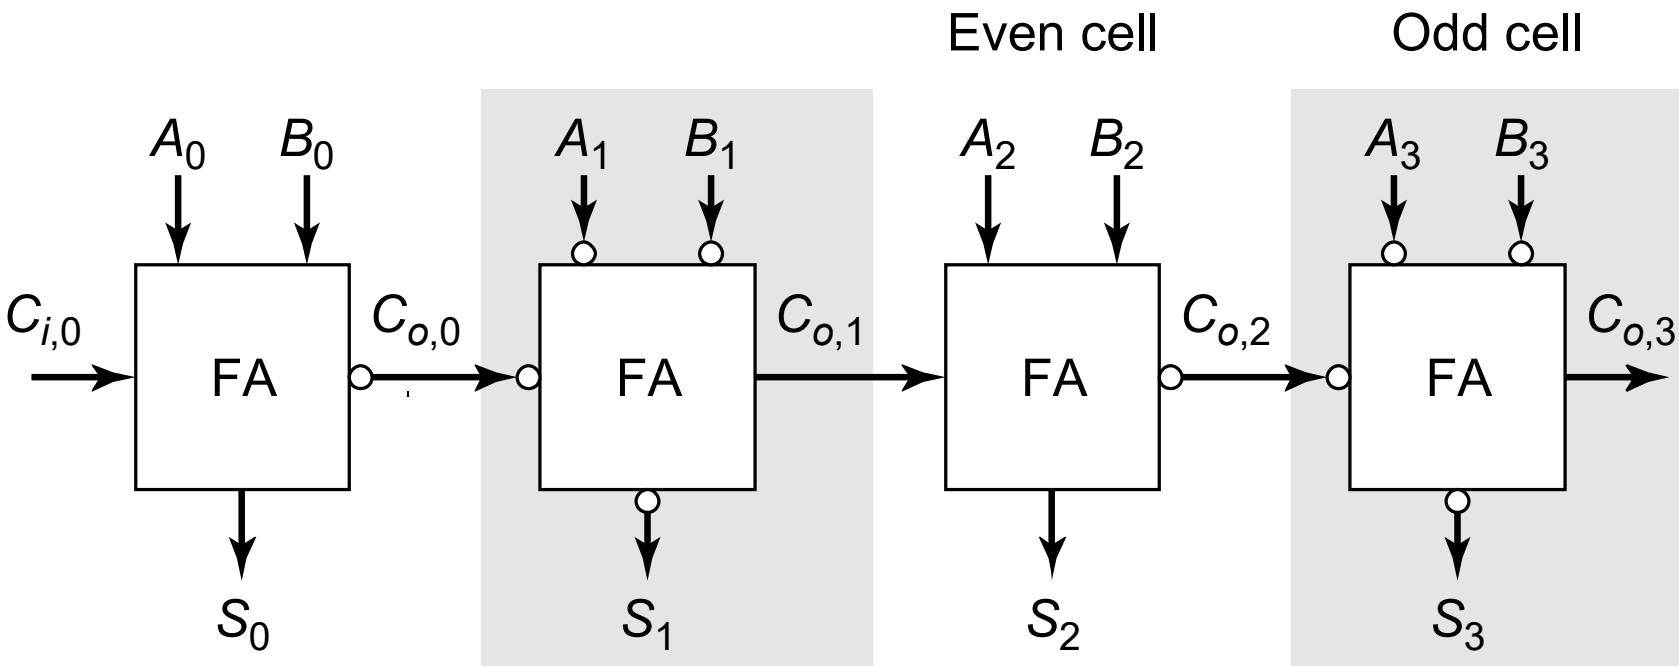


$$\overline{S}(A,B,C_i) = S(\overline{A},\overline{B},\overline{C}_i)$$

$$\overline{C}_0(A,B,C_i) = C_0(\overline{A},\overline{B},\overline{C}_i)$$

Inverting all inputs to FA results in inverted values for all outputs

Minimize Critical Path by Reducing Inverting Stages

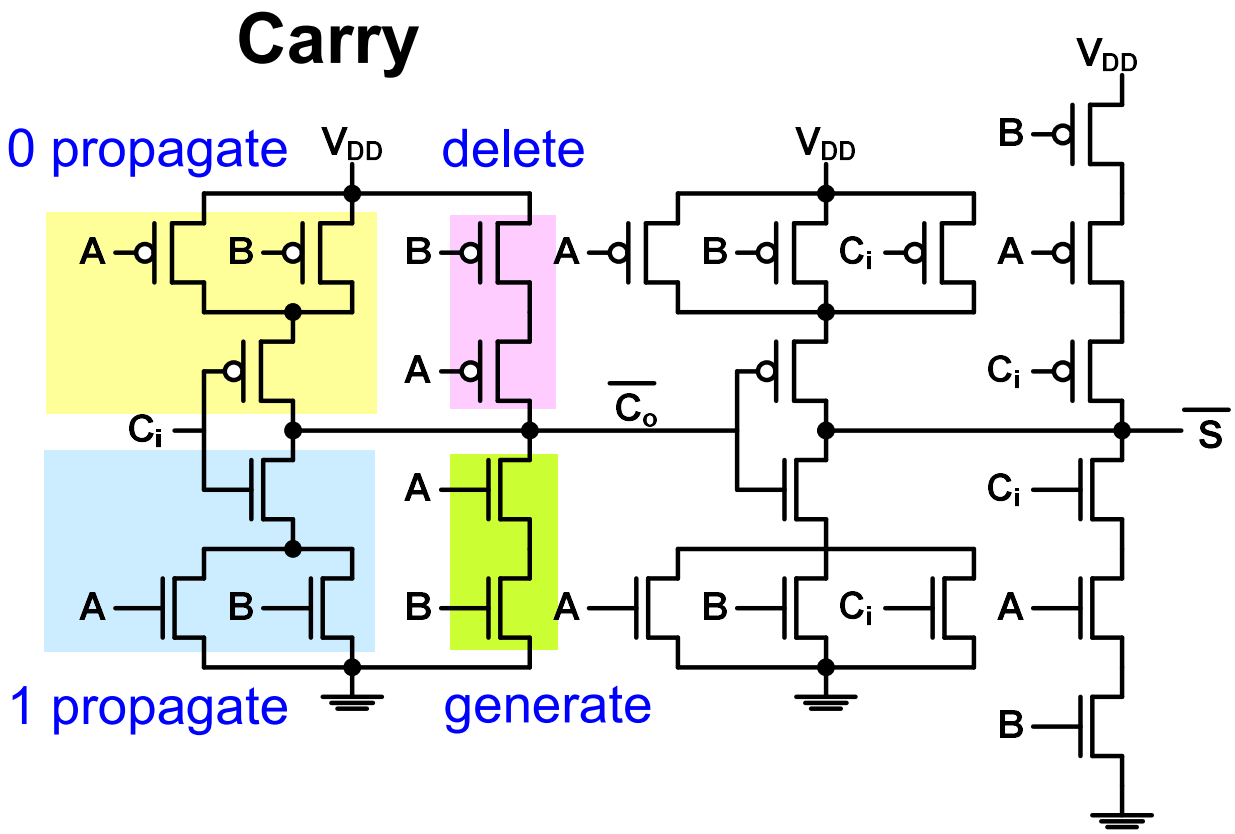


Exploit Inversion Property

Mirror Adder (1)

A	B	C_i	S	C_o	status
0	0	0	0	0	D
0	0	1	1	0	D
0	1	0	1	0	P
0	1	1	0	1	P
1	0	0	1	0	P
1	0	1	0	1	P
1	1	0	0	1	G
1	1	1	1	1	G

Truth Table for Full Adder

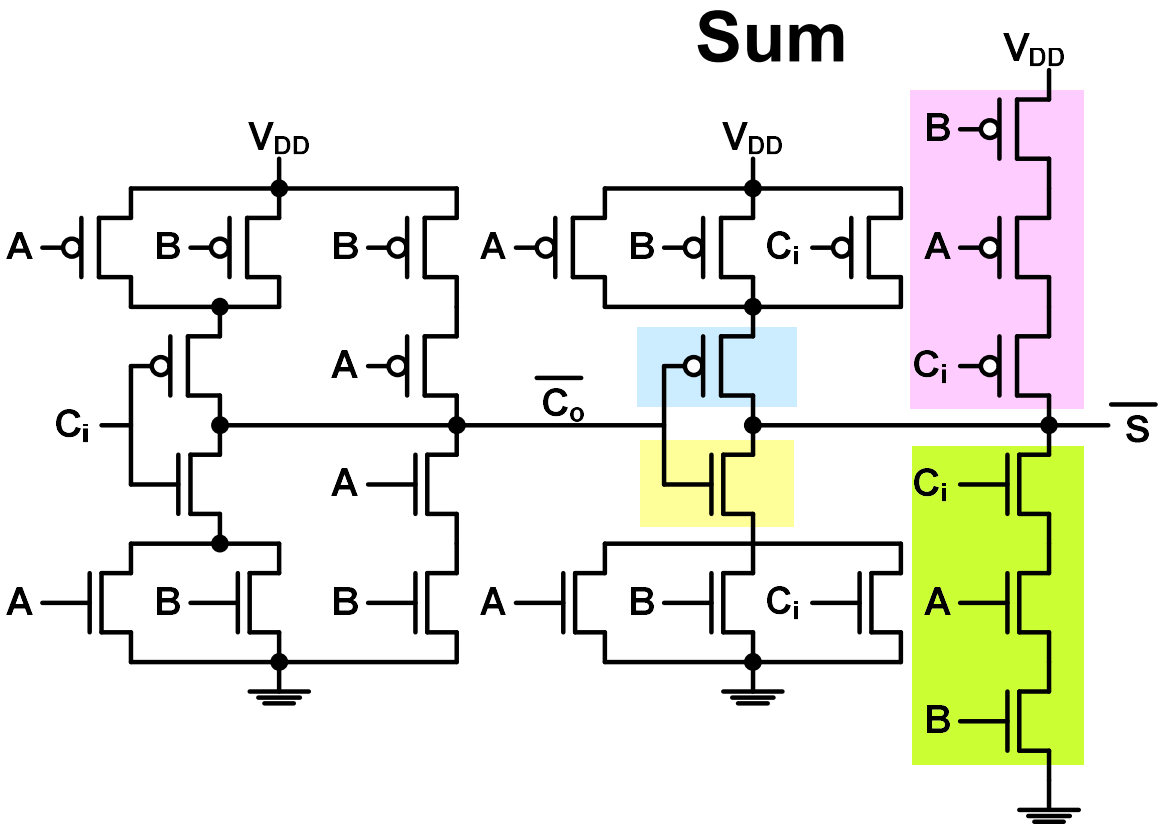


- Carry-inverting gate is eliminated
- PDN/PUN networks are not dual

Mirror Adder (2)

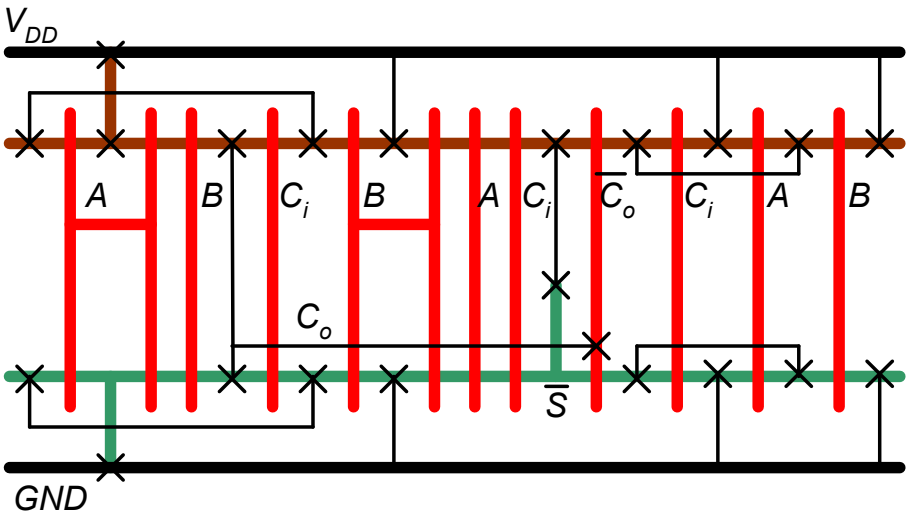
A	B	C_i	S	C_o	status
0	0	0	0	0	D
0	0	1	1	0	D
0	1	0	1	0	P
0	1	1	0	1	P
1	0	0	1	0	P
1	0	1	0	1	P
1	1	0	0	1	G
1	1	1	1	1	G

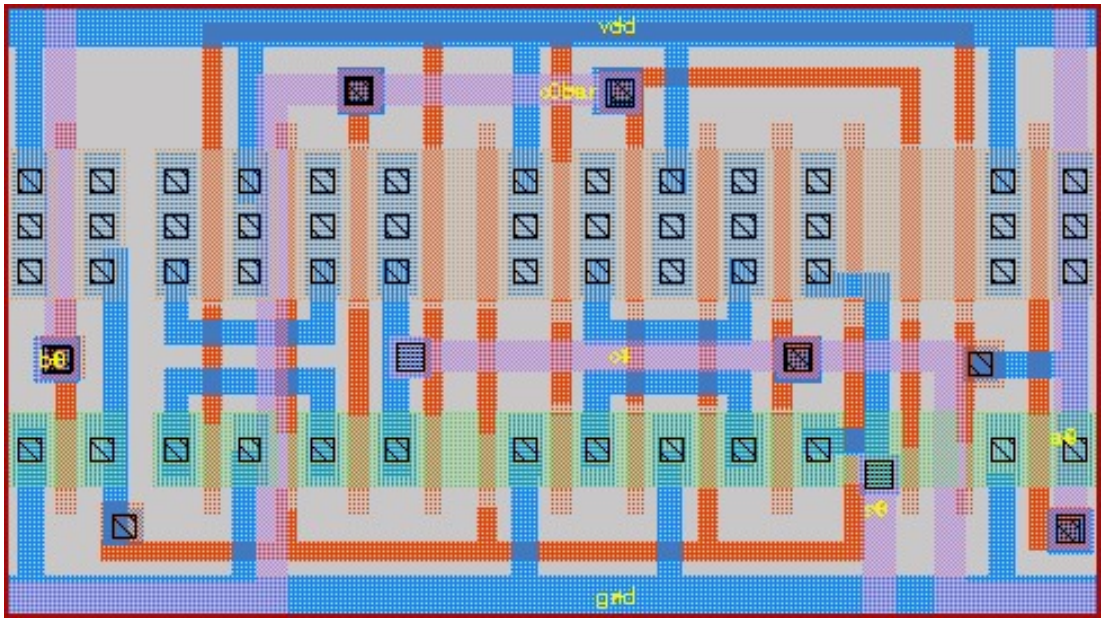
Truth Table for Full Adder



Mirror Adder Implementation

Stick Diagram

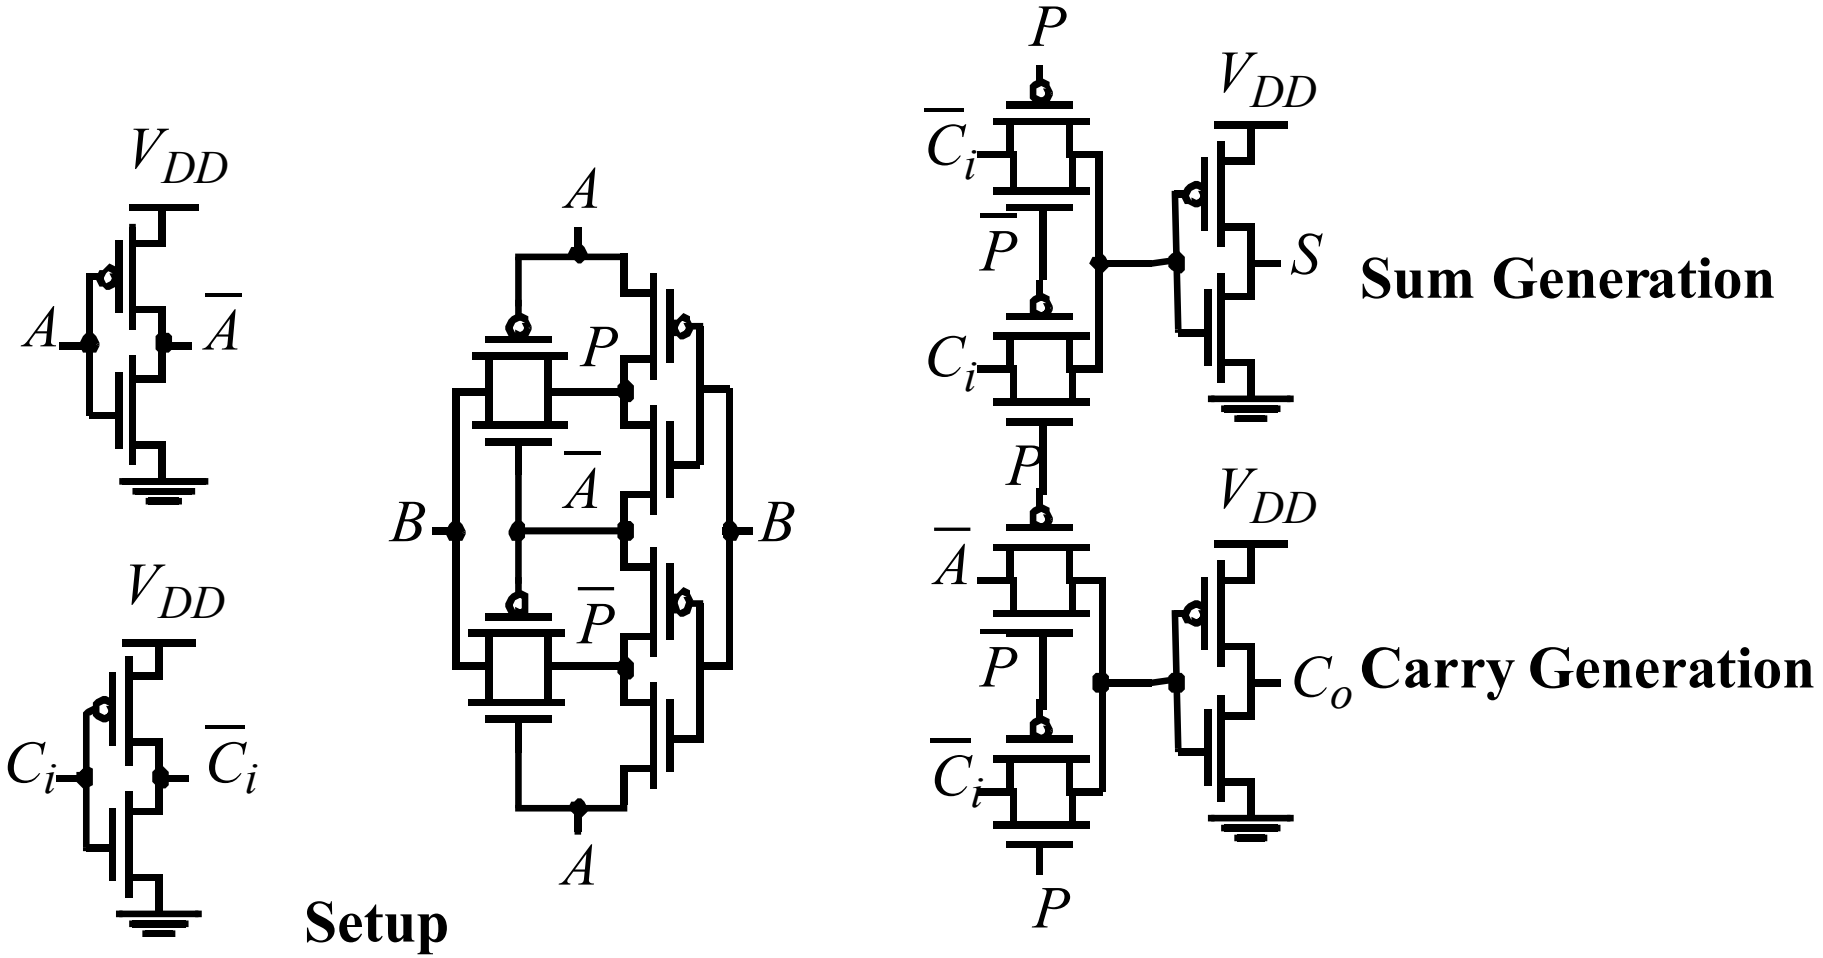




Mirror Adder Summary

- 24 Transistors
- The NMOS and PMOS chains are completely symmetrical
- A maximum of 2 series transistors in carry-generation circuitry
- The transistors connected to C_i should be closest to the output
- Carry-Stage transistors have to be optimized for speed
- Sum-Stage transistors can be optimized for area
- The most critical issue is to minimize the capacitance at C_o
- C_o is composed of 4 diffusion capacitances, 2 internal gate capacitances, and 6 gate capacitances in the connecting adder cell

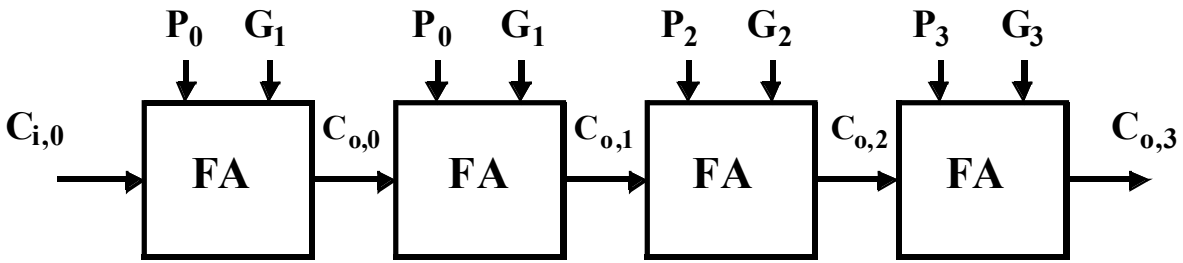
Transmission Gate Full Adder

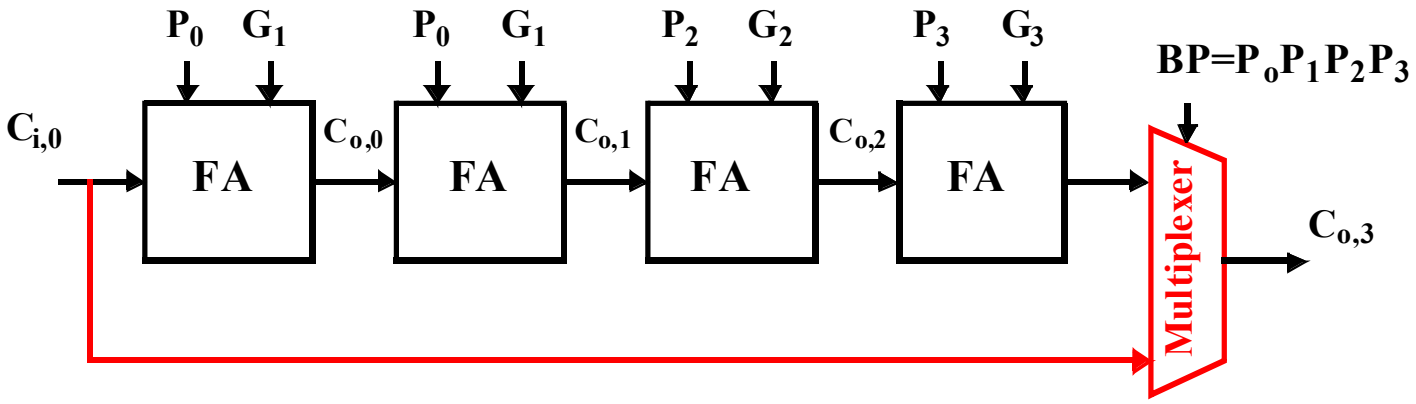


This implementation has similar sum and carry output delay

Carry-Bypass Adder

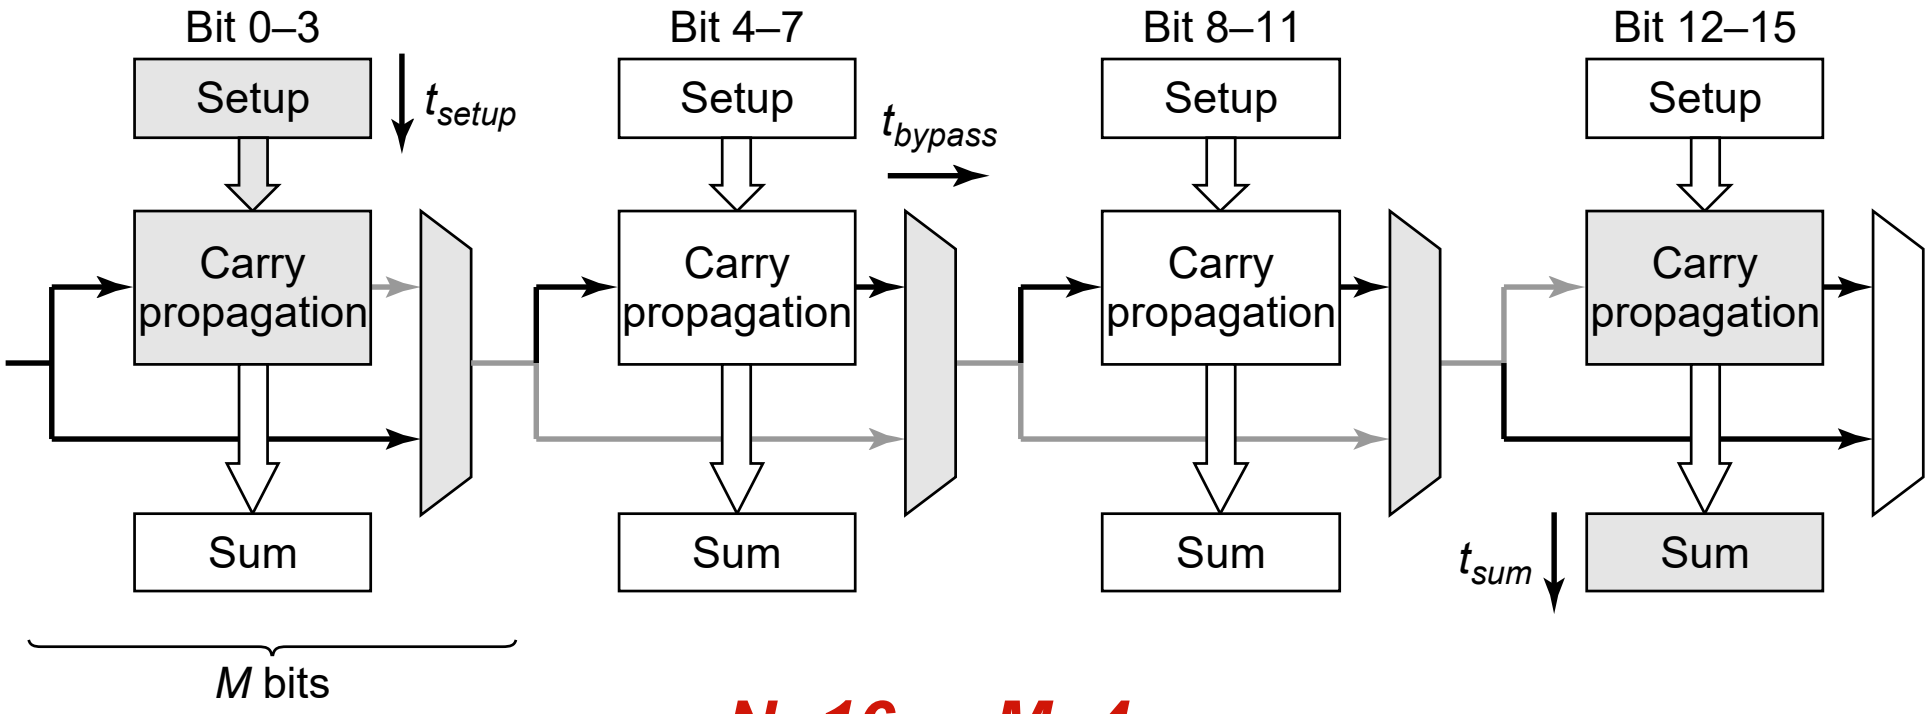
Carry-Skip Adder





Idea: If (P0 and P1 and P2 and P3 = 1) then $C_{o3} = C_0$, else "kill" or "generate".

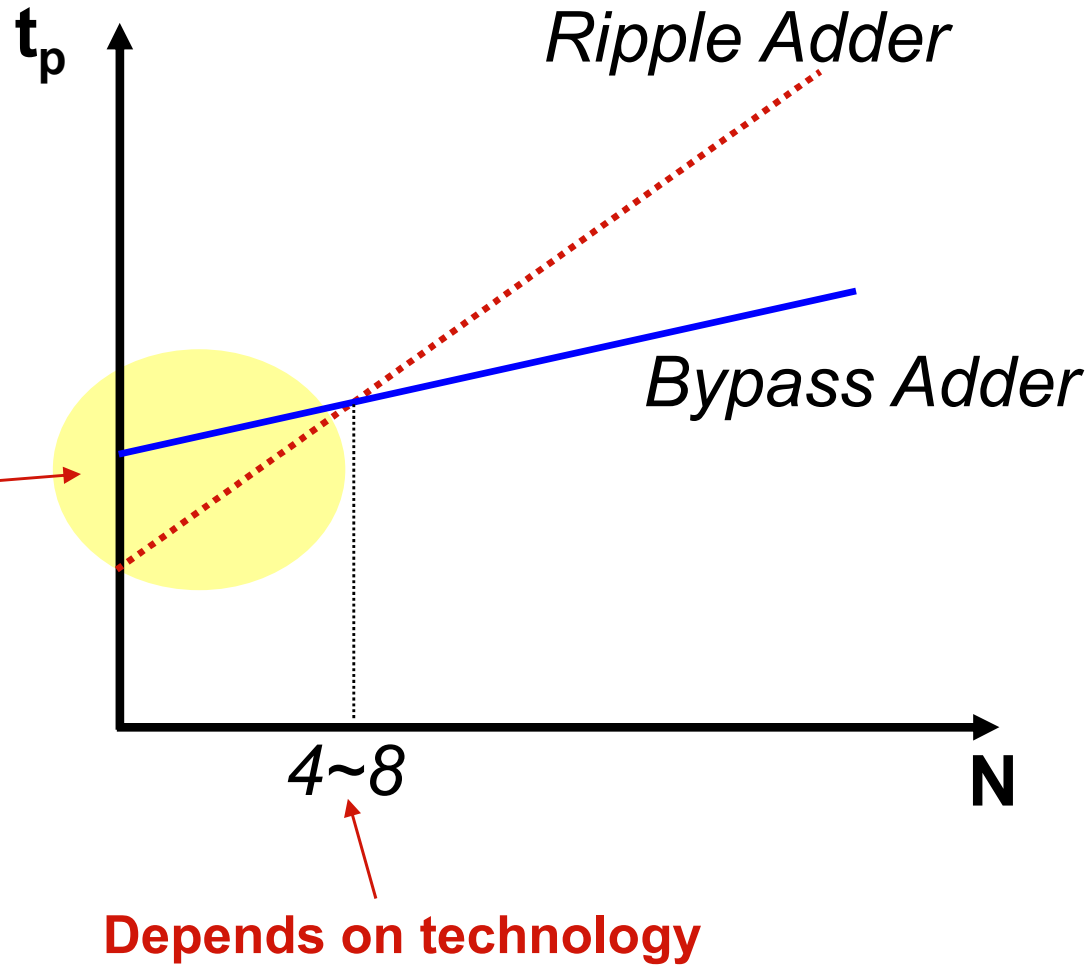
16-bit Carry-Bypass Adder



N=16 M=4

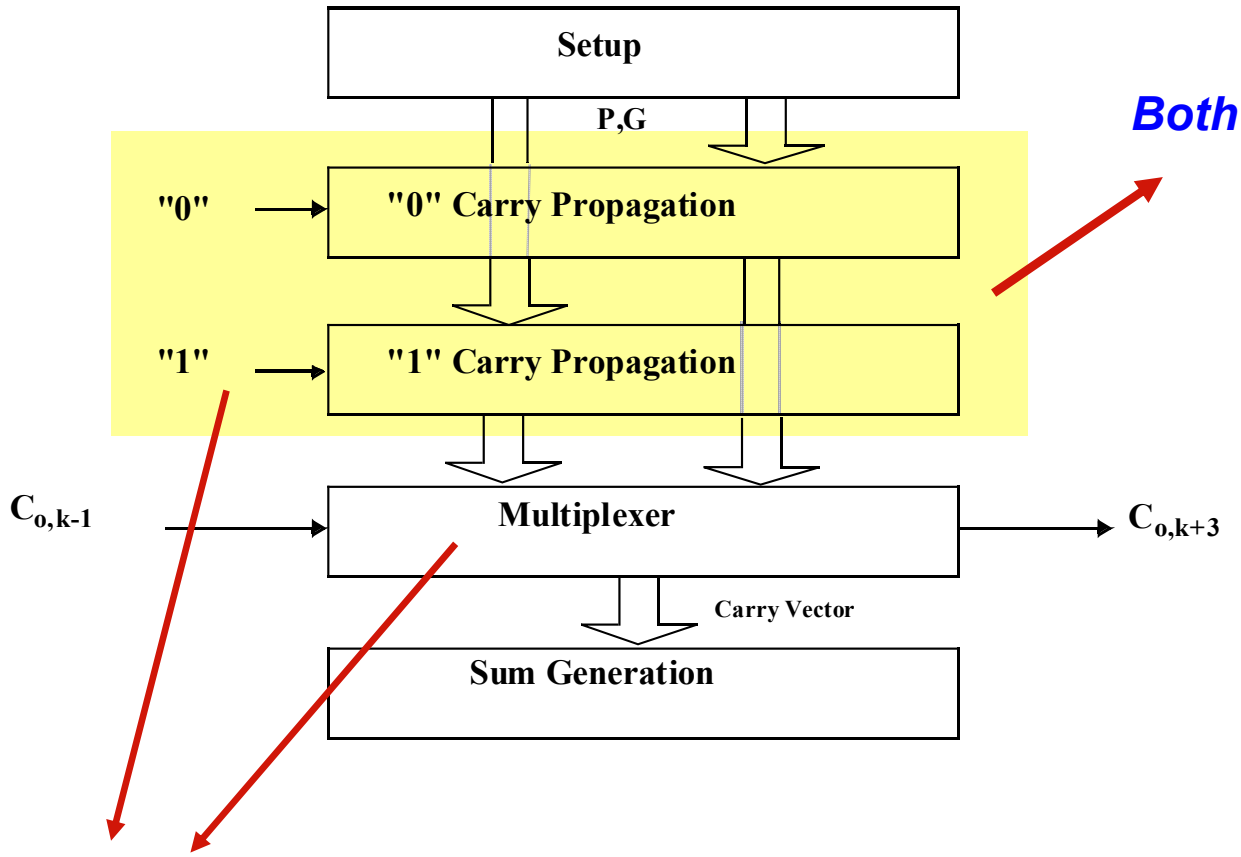
$$t_{adder} = t_{setup} + Mt_{carry} + (N/M\text{-}1)t_{bypass} + (M\text{-}1)t_{carry} + t_{sum}$$

Carry Ripple versus Carry Bypass



For smaller N, bypass adder is not preferred due to the overhead of bypass multiplexer

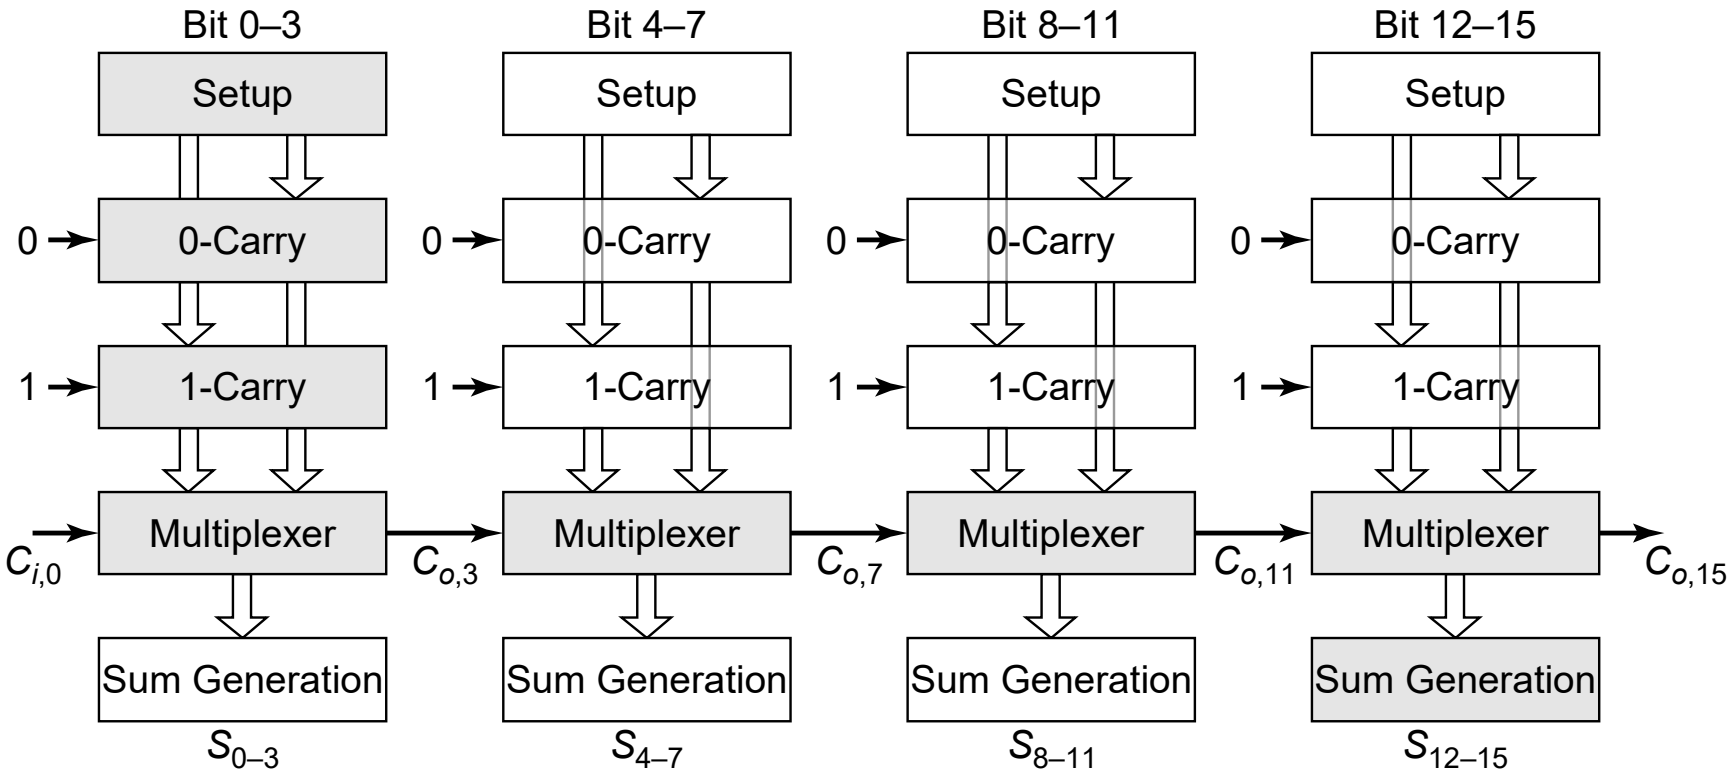
Linear Carry-Select Adder



Both situations are evaluated

~ 30 % Hardware overhead

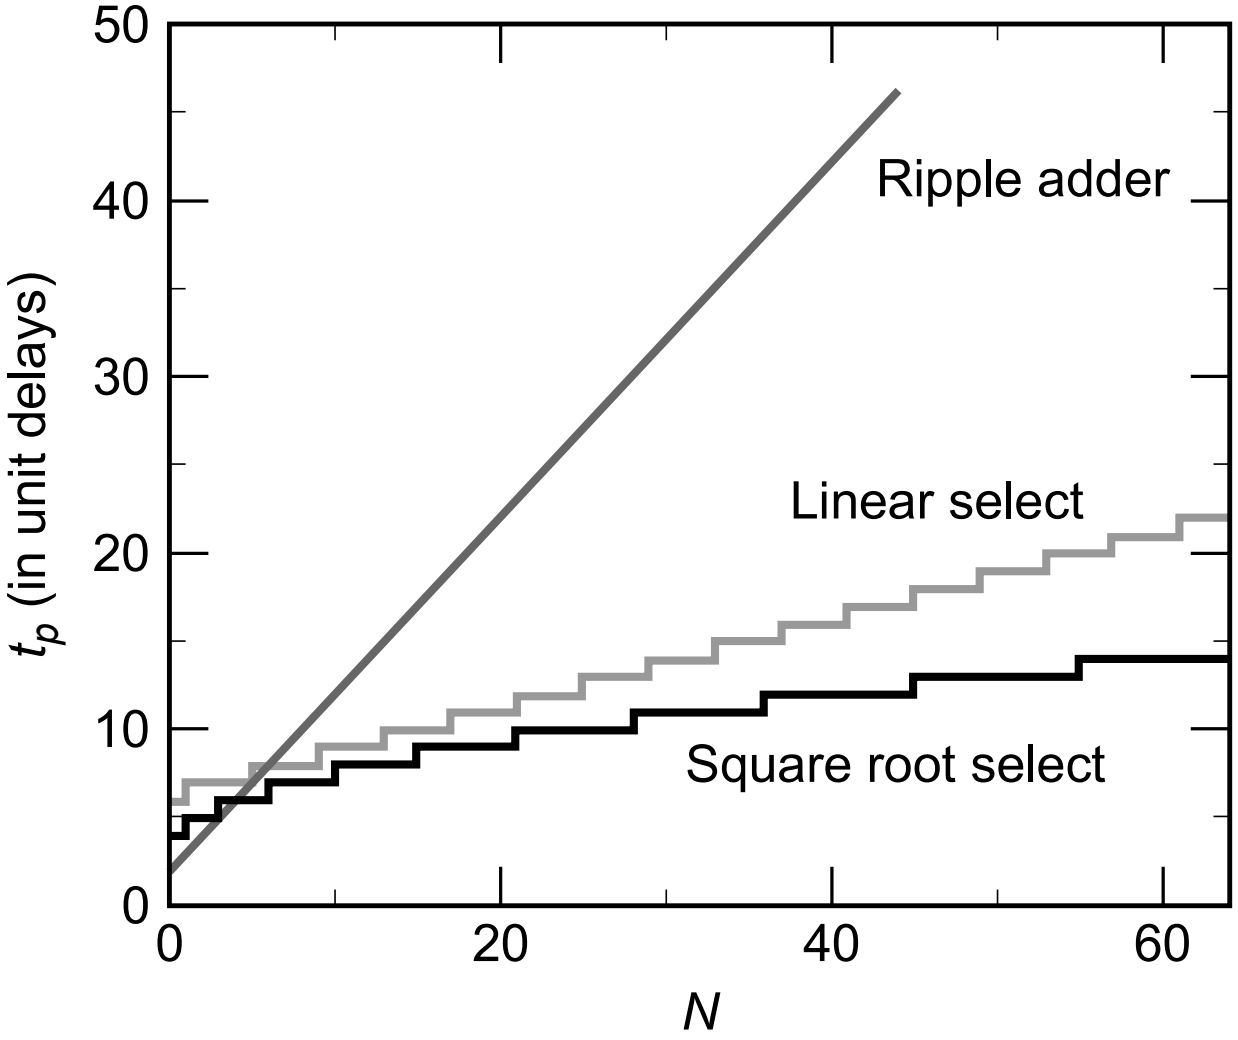
16-bit Linear Carry-Select Adder



N=16 M=4

$$t_{adder} = t_{setup} + Mt_{carry} + (N/M)t_{mux} + t_{sum}$$

Adder Delays - Comparison

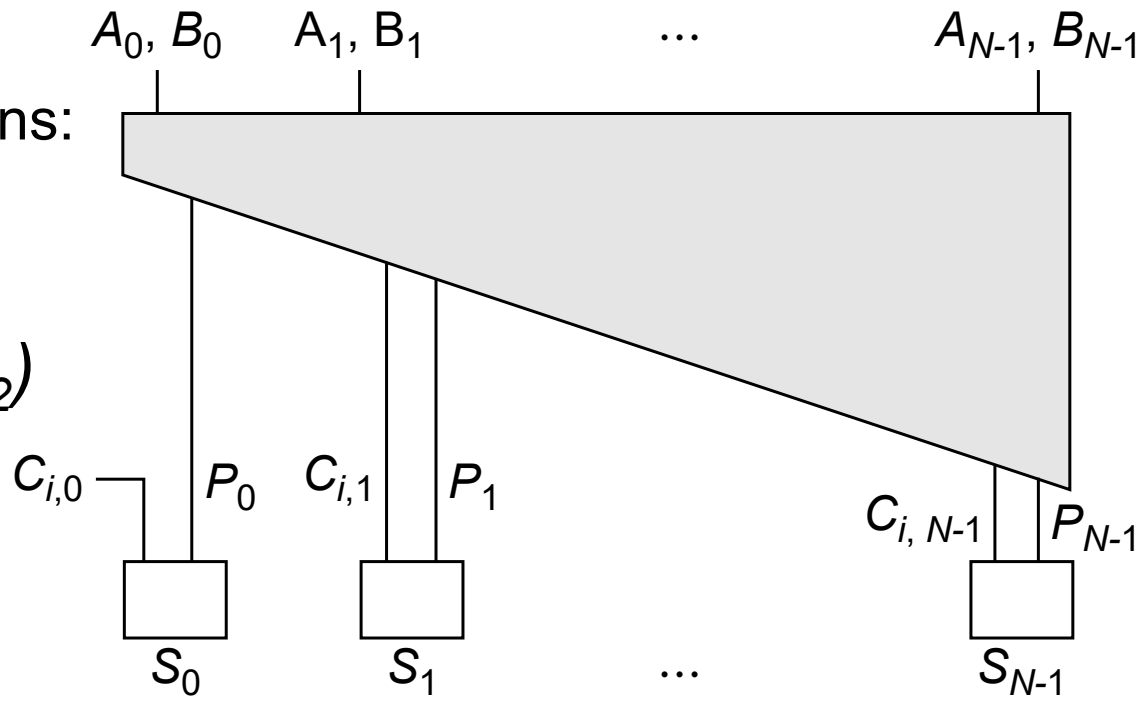


Look-Ahead - Basic Idea

Expanding Lookahead equations:

$$C_{0,k}=G_k+P_kC_{0,k-1}$$

$$C_{0,k}=G_k+P_k(G_{k-1}+P_{k-1}C_{0,k-2})$$



All the way:

$$C_{0,k}=G_k+P_k(G_{k-1}+P_{k-1}(\ldots\ldots+P_1(G_0+P_0C_{i,0})))))$$

Carry Determination

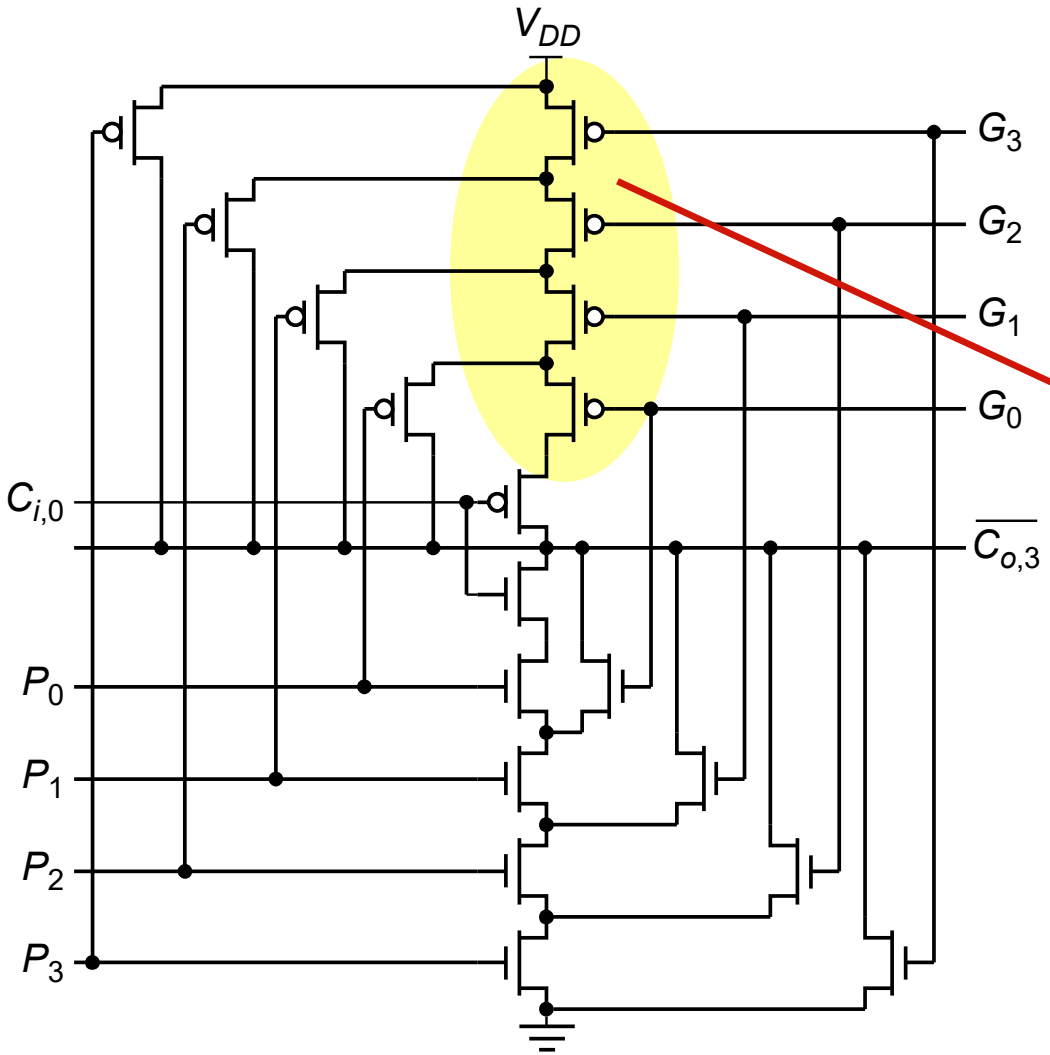
$$C_{o,0}=G_0+P_0C_{i,0}$$

$$C_{o,1}=G_1+P_1C_{o,0}=G_1+P_1(G_0+P_0C_{i,0})=G_1+P_1G_0+P_1P_0C_{i,0}$$

$$C_{o,2}=G_2+P_2G_1+P_2P_1G_0+P_2P_1P_0C_{i,0}$$

$$C_{o,3}=G_3+P_3G_2+P_3P_2G_1+P_3P_2P_1G_0+P_3P_2P_1P_0C_{i,0}$$

4-bit Look-Ahead

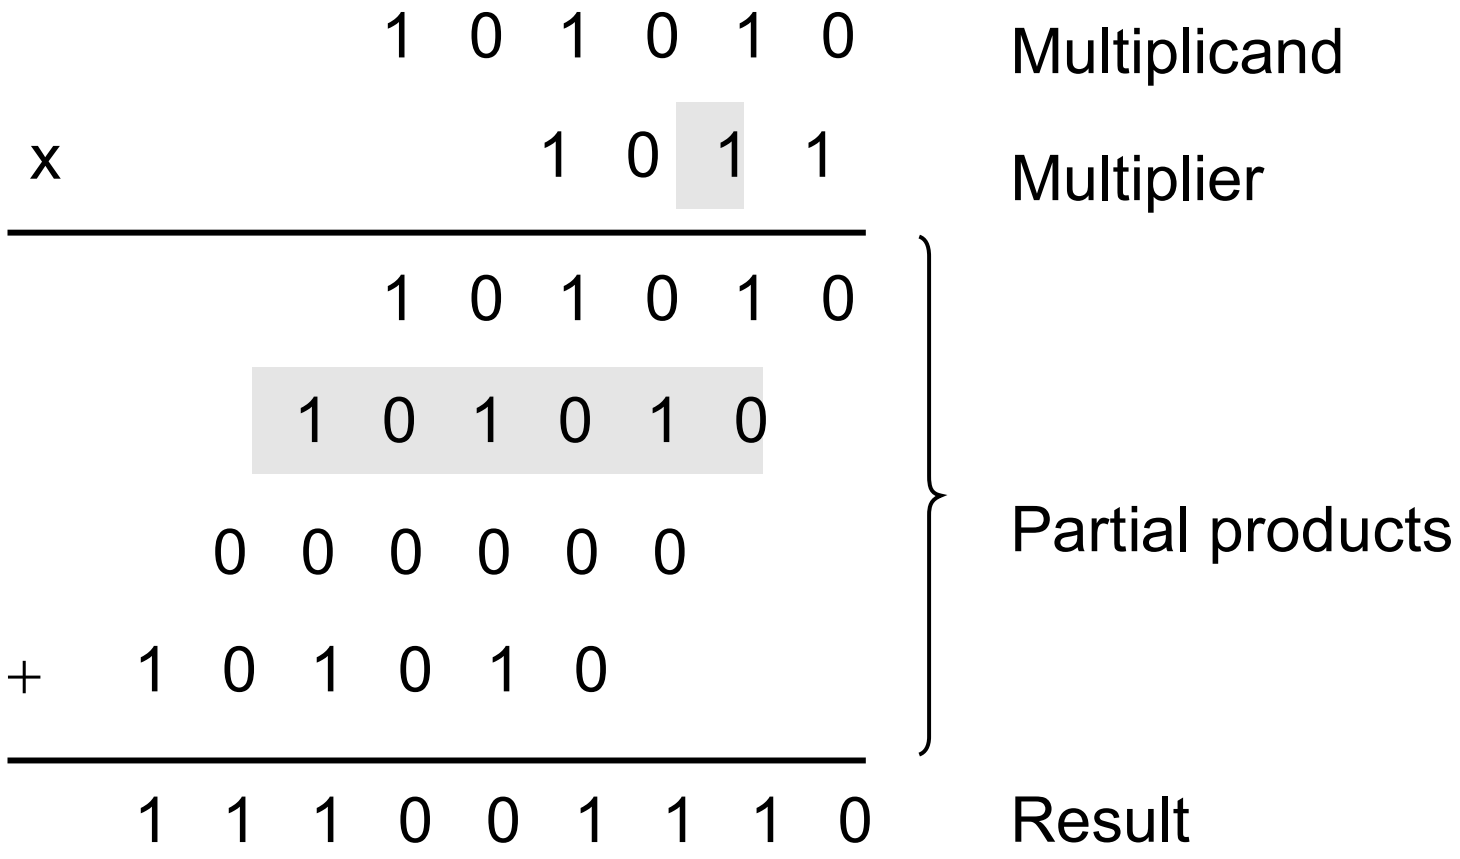


Large stack

Poor Performance

Multipliers

The Binary Multiplication



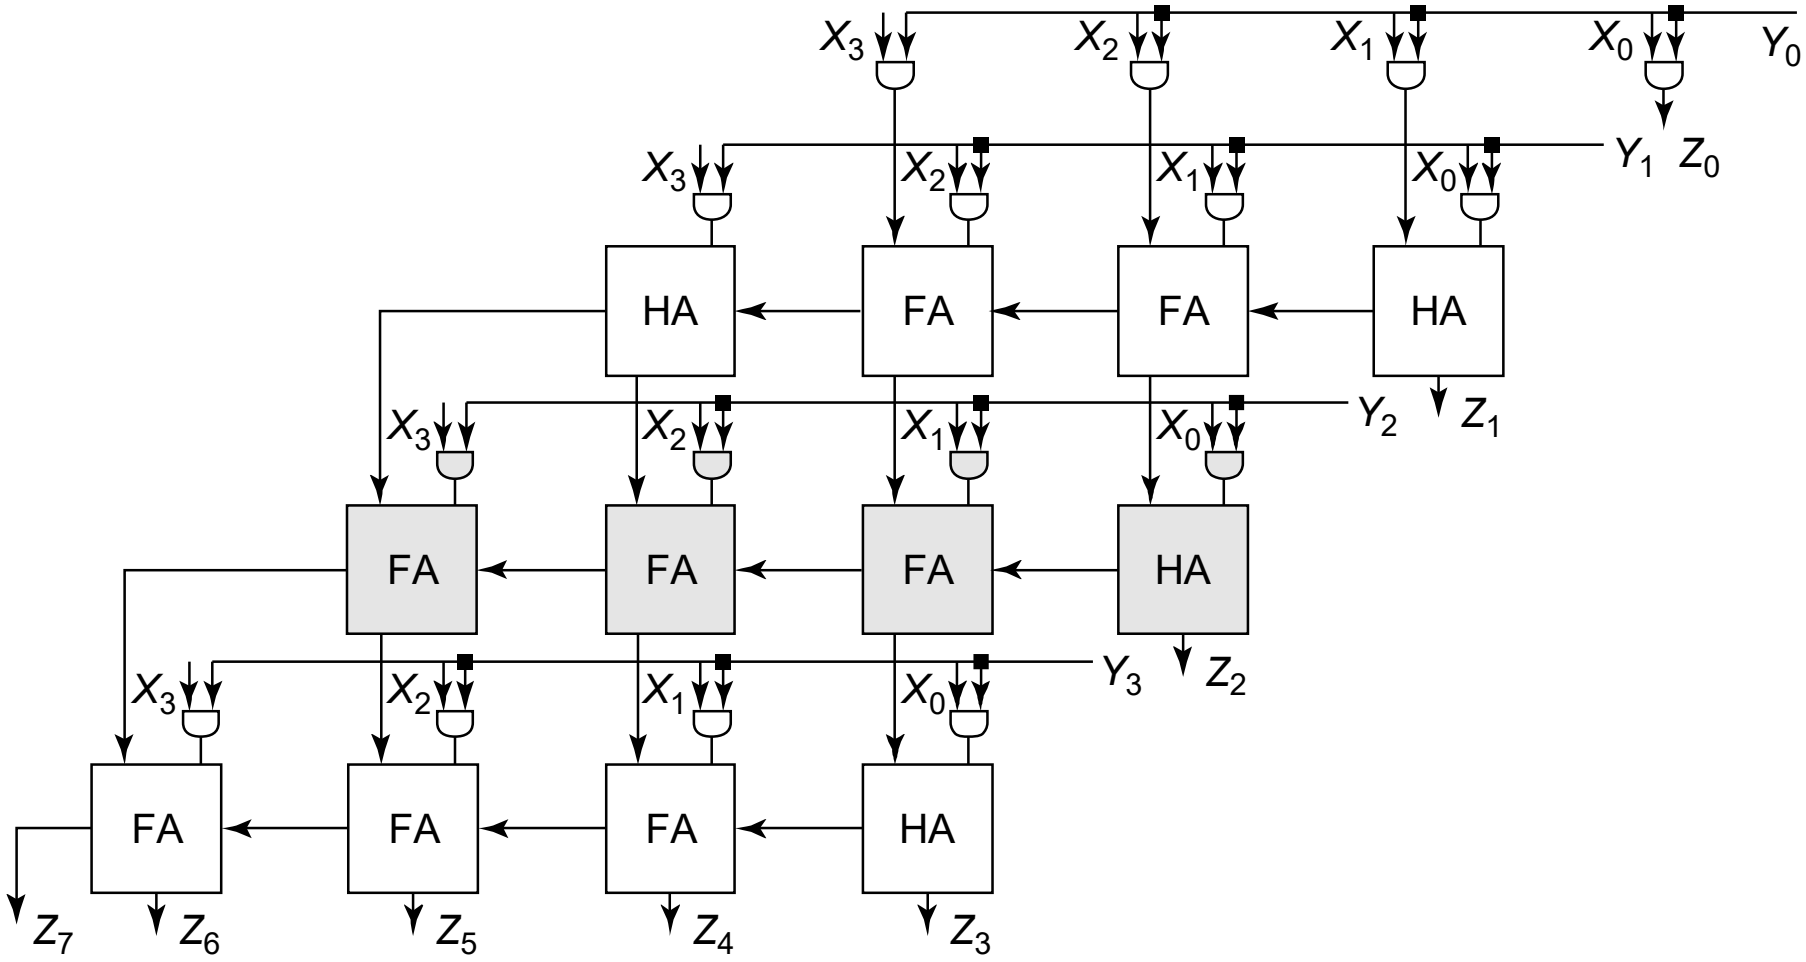
Reduce Partial Products

- Partial products can be reduced by multiplier transformation

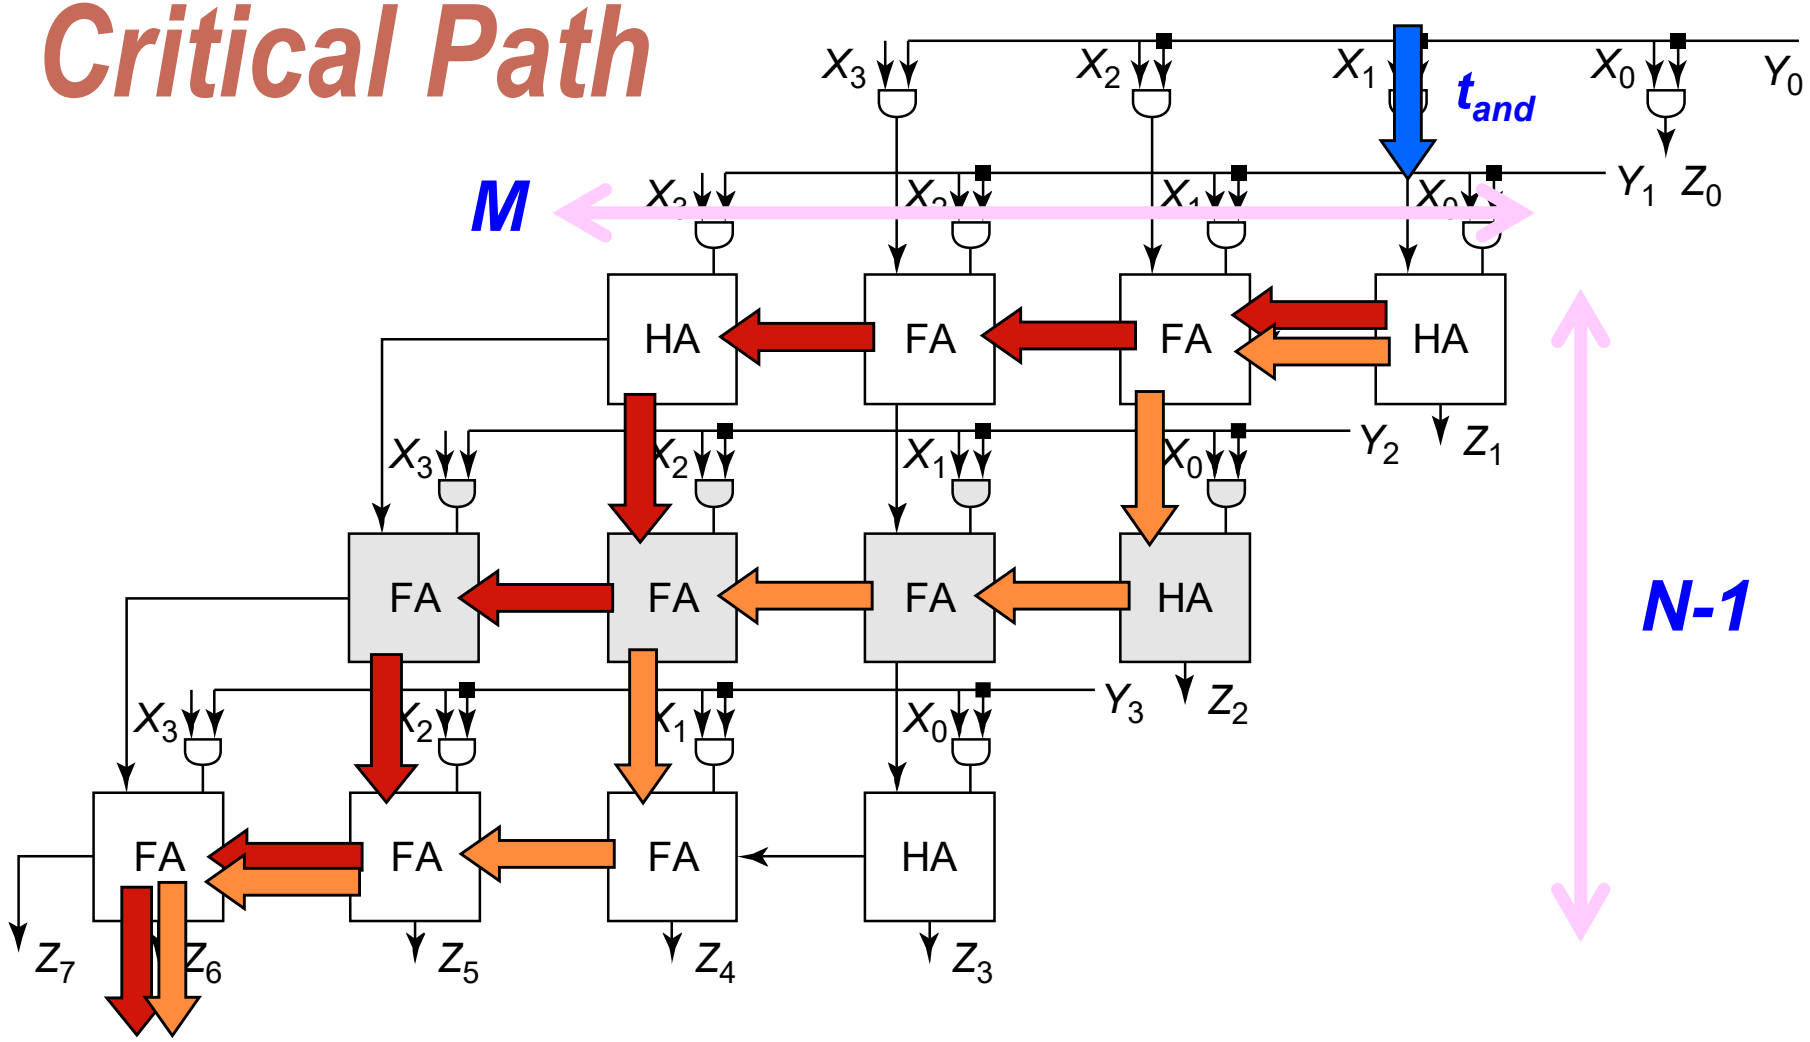
  (Booth's Recording)

- Reduce number of partial products is equivalent to reducing the number of additions

4X4 Bit-Array Multiplier



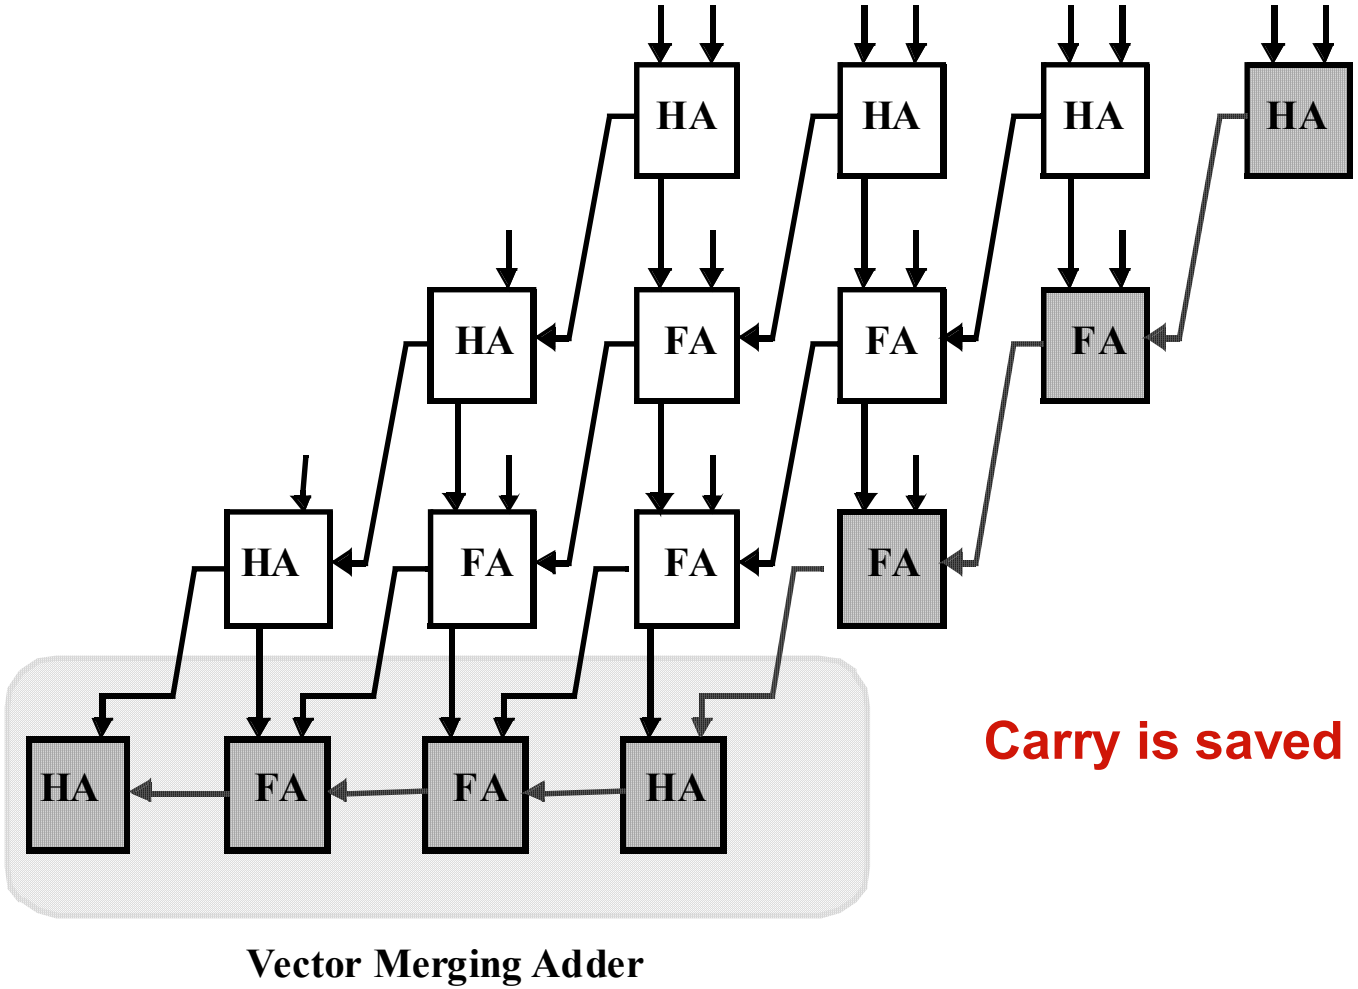
Critical Path



For MXN Bit-Array Multiplier

$$t_{multiplier} = [\,(M-1) + (N-2)\,]\,t_{carry} + (N-1)\,t_{sum} + t_{and}$$

Carry-Save Multiplier

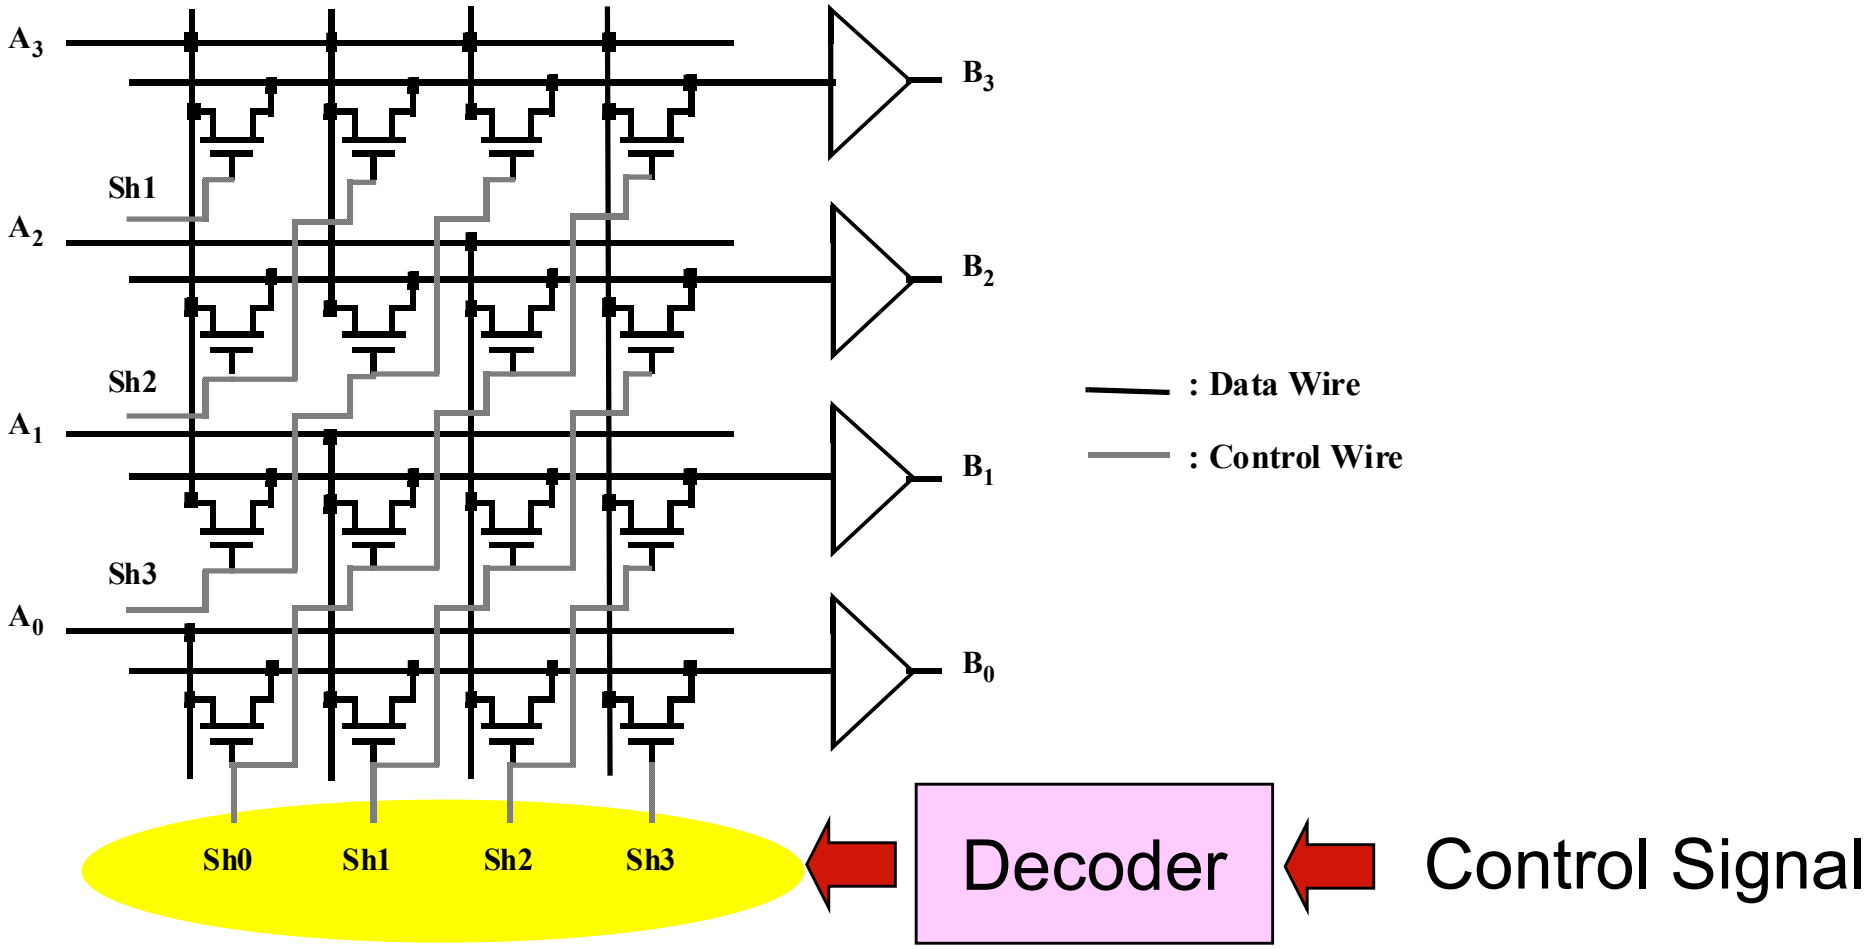


Carry is saved for the next adder stage

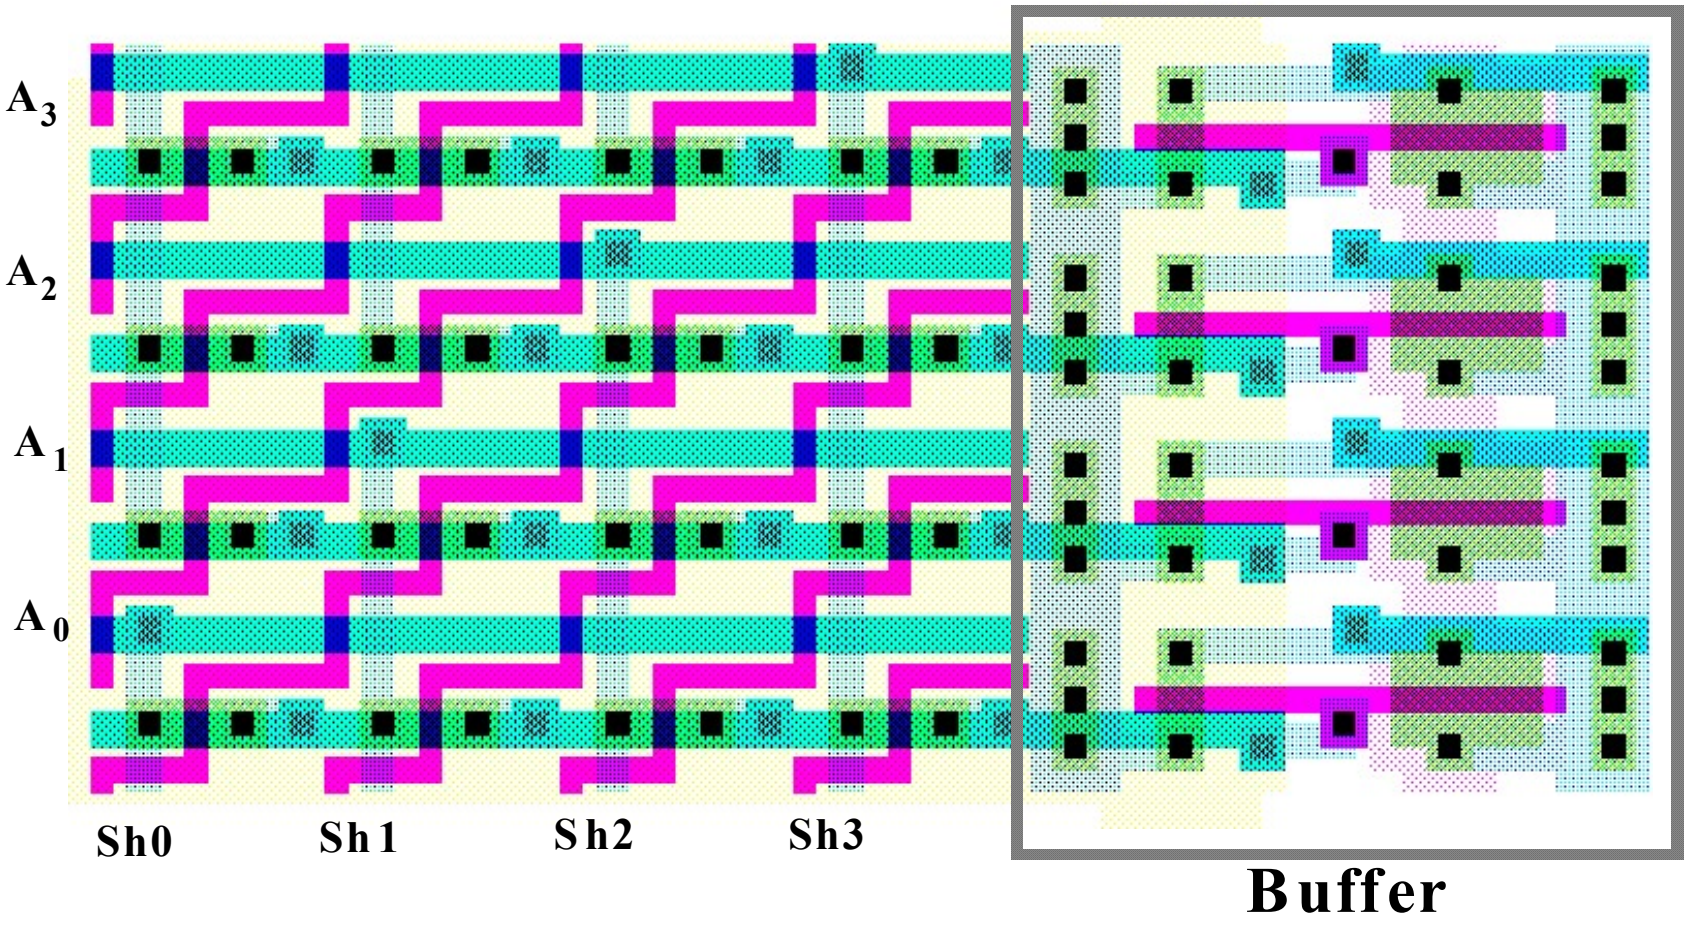
$$t_{multiplier} = (N-1)\, t_{carry} + t_{and} + t_{merge}$$

The Barrel Shifter

Area Dominated by Control Wiring

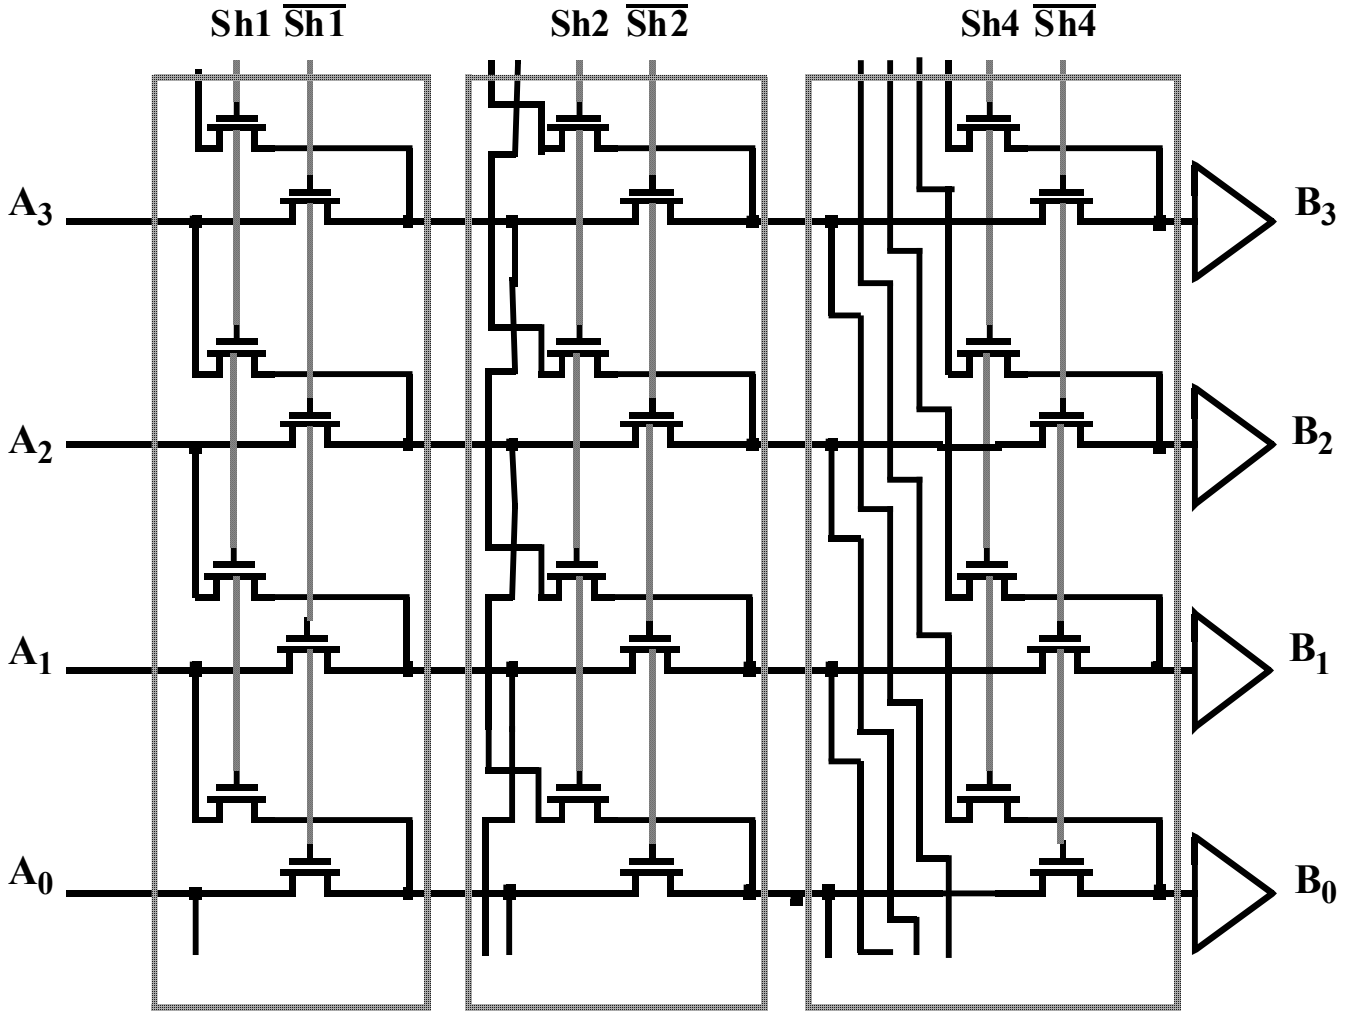


4x4 barrel shifter



$$\text{Width}_{\text{barrel}} \sim 2\, p_m\, M$$

Logarithmic Shifter



0-7 bit Logarithmic Shifter
